RECTAL SYMPTOMS FROM THE GENERAL SURGEON'S STANDPOINT

HARVEY B. STONE, M.D.

BALTIMORE

The greater part of all rectal surgery is done by the general surgeon, and practically all general surgeons do rectal work. At the same time, it is true that most of these men regard rectal work as a subordinate part of their practice. They are not especially interested in it and are not particularly adept at the making of rectal examinations. It is not improbable that a considerable number do not possess a proctoscope and are unskilled in the use of the instrument. Under such circumstances a review of the significance of rectal signs and symptoms would seem worth while. There is nothing of great novelty to be expected in such a discussion, but clarification and emphasis on clinical facts have a value as practical if not as striking as novelty.

The signs and symptoms that accompany rectal disorders may be grouped under comparatively few headings: sensory disturbances, abnormal secretions or discharges, disturbances of defecation, anatomic changes. The duration of any of these derangements and their intensity are also of important bearing in many cases. By asking specific and searching questions regarding each of these items, one may usually build up a clinical picture that aids greatly in making a diagnosis. The more common of the rectal lesions will be presented from this standpoint, in synoptic form, with brief comments.

The first point to be emphasized is that no single symptom is pathognomonic of any single rectal lesion. For instance, pain occurs with fissure, abscess, thrombosed hemorrhoids and penetrating foreign bodies. Bleeding occurs with internal hemorrhoids, polyps and papillomas, ulcerative colitis and cancer. Secondly, lesions that are entirely different in their pathologic nature may present a very similar symptom complex. Thus, ulcerative colitis and carcinoma of the rectum may each cause the passage of blood and mucus in the stool, frequent and urgent desire to defecate, loss of weight, and abdominal, crampy pains. The explanation, of course, lies in the fact that these very different lesions have in common an ulcerating surface, an irritative stimulus to the defecation reflex and a disturbing effect on nutrition. In the third place, conditions that may be quite different in fact may be described by patients in identical terms. When a patient states that he notices a discharge or secretion or moisture about the anus, he may refer to the pus from a fistula, the

mucus from everted hemorrhoids, the discharge from an infected pilonidal sinus or the serous weeping of pruritus ani.

It may seem from what has been said that there is not much diagnostic significance to be attached to the patient's various rectal complaints, yet this is not the case. Many rectal disorders have a quite characteristic symptom complex. The difficulty in eliciting a description of it lies in the widespread habit of patients of being vague in their complaints and description of rectal disturbances. "Rectal trouble" and "hemorrhoids" are the initial statements of so many that one comes to expect them. Even when it is pointed out that these statements are unsatisfactory, the patient often seems unable to put into words a satisfactory description of what ails him. Hence, it becomes necessary to ask a series of pointed and exact questions that for the most part call for a "yes" or "no" answer. Not infrequently, with certain patients, this searching inquisition may become a bit irksome both to examiner and to deponent, but it amply repays persistence. One should cover the general headings of sensory disturbances, abnormal discharges, alteration of bowel habits and anatomic abnormalities first, and then any admitted deviation from normal should be elucidated by means of a number of detailed questions. For example, suppose that a patient complains of pain. One then asks whether the pain is dull or sharp, brief or persistent, related to the passage of stool or to any other definite act, of recent occurrence or long standing, abrupt or gradual in development, relieved by any treatment yet tried, referred to other parts of the body, or associated with other symptoms under the other general headings of discharges, bowel changes or anatomic abnormalities. These headings are then taken up in a similarly exhaustive manner. After perhaps five minutes of such questioning one learns all that the patient has to tell of his own observations on his illness. It is surprising how often there emerges a picture so characteristic that one may almost make a diagnosis by it alone. Some of the characteristic symptom complexes are so frequent that they merit a condensed description.

Pain beginning with defecation and lasting for from many minutes to several hours afterward, of a gnawing, burning or biting character, with a little bleeding at infrequent intervals, with a small protruding tag, tightness of the sphincter muscle and a tendency to constipation, the whole condition lasting for a number of weeks and getting worse, spells fissure in ano. Pain beginning suddenly a day or a few days before, severe, stinging and aching, quickly reaching a maximum and persisting steadily without relation to defecation and without throbbing accompanied by the sudden appearance of a hard, tender lump at the anal margin, little or no bleeding and no noteworthy alteration of bowel

habits, indicates a thrombosed marginal hemorrhoid. A history of swelling that appeared near the anus some time previously—perhaps a few weeks, perhaps several years ago—with dull throbbing pain and soreness, that broke or was opened and has discharged pus since then, usually means a fistula. These characteristic clinical pictures are familiar to most surgeons. A few rare conditions are equally characteristic. A sudden, severe gripping pain in the anus, coming on abruptly, entirely without apparent cause, often in the night awaking the patient from a sound sleep, occurring at irregular and sometimes long intervals, lasting a few minutes, promptly relieved by the application of heat, with no other related symptoms whatever, is typical of rectal neuralgia. A sudden, severe stabbing pain in the anus, continuous and unremitting, starting during the act of defecation, with no previous history of trouble and not accompanied by other symptoms, is usually due to the penetration into the anal wall of some swallowed sharp foreign body.

However, not all rectal lesions have characteristic stories. For instance, the two cardinal features of hemorrhoids are bleeding and protrusion. It should be noted in parenthesis that pain occurs only when some complication, such as thrombosis, ulceration or infection, has developed. But the cardinal features of anal and low rectal polyps and papillomas are also bleeding and protrusion. As was mentioned earlier in the article, there is a certain general similarity in the complaints presented by patients who are suffering with ulcerative colitis or proctitis and by those who have rectal cancer. This leads one to the inevitable conclusion that, valuable as a competent and searching analysis of the patient's complaints undoubtedly is, there is something more essential to a proper investigation of rectal conditions, and that additional something is the making of a proper local examination.

The making of a rectal examination requires a good light, the knee-chest or Haynes position, the performance of a careful digital examination and inspection of the interior of the rectum with a proctoscope. All these requirements are easily within the attainment of the general surgeon. It is true, of course, that the rectal specialist will have greater skill and familiarity in such procedures than the surgeon who employs them only occasionally, but if one undertakes to do rectal surgery at all, as most general surgeons do, it is incumbent on one to acquire at least sufficient skill in rectal examination to avoid gross errors of diagnosis. The rectal specialist or proctologist who is also a competent surgeon will remain in a position of advantage in the handling of rectal diseases because of his superior training and experience in this special field. He will be the consultant for advice and treatment in unusual cases from far and near and in his own locality may properly expect to be preferred over the general surgeon for the ordinary run of rectal conditions. But in many communities there are no specially trained proctologists, and the general surgeon must care for rectal diseases along with his general surgical work. I am a general surgeon, but one especially interested in rectal diseases, and I have been impressed with the opportunity for improvement in the field of rectal work on the part of general surgeons. A fuller understanding of the significance of rectal complaints and the development of experience in the technique of rectal examinations will ensure this desirable improvement.

18 West Franklin Street

ABSTRACT OF DISCUSSION

DR. CURTICE ROSSER, Dallas, Texas. I have no ground for disagreement with Dr. Stone's premises. The suggestion that the general surgeon who desires to include proctologic lesions in his operative field shall first equip himself with an armamentarium of mental interest and physical diagnostic equipment is self-explanatory and entirely logical. The value of a digital examination has perhaps been oversold to the profession in a praiseworthy attempt to popularize a neglected but simple diagnostic aid. Unfortunately, blind palpation will not distinguish between bleeding amebic ulceration and bleeding hemorrhoids, for example. The trend of present statistical information, moreover, leads one to believe that two thirds of all rectal cancers are in their early stages beyond the reach of the probing finger, and here again a simple digital examination gives the surgeon a sense of false security which an instrumental examination would dispel. Moreover, the rectosigmoid canal is a blind spot to the roentgen ray. Many years ago, William Osler acknowledged the benefit derived by medicine in general from the concentration of effort on the part of those who in the bewildering complexity of modern medical science find relief in the limitation of the work of their lives to some comparatively narrow field that could be thoroughly tilled. The satisfaction that many men derive from the mastery of even a small department, particularly one in which technical skill is required, would be enhanced if by the free interchange of the fruits of experience and knowledge which our craft encourages they could know that the broader divisions of medicine were somewhat advanced. No medical man refuses to accept the considered observations of competent laboratory workers. The various surgical specialties from their own small areas could pass on to general surgery and to one another certain well-proved concepts in surgical technique as well as diagnostic methods. To be more specific, the proctologist, grateful to the surgical preceptors who give him fundamental surgical training, should reciprocate by aiding the general surgeon in connection with the management of anal lesions, encouraging him to discard the routine use of the cautery in anorectal lesions, attempting to convince him that divisions of the sphincter muscles has only long usage to commend it, and encouraging the basic concept that the same diagnostic care, adherence to anatomic zones and gentleness in handling delicate tissues are indicated in the anorectum as the surgeon is accustomed to employ in the other areas of the body.

DR. FRANK C. YEOMANS, New York. Dr. Stone's paper outlines clearly the significant symptoms and procedure for the recognition of rectal diseases. In taking the history, one should bear in mind the possibility of amebic infection. In each of two men referred to me with the diagnosis of rectal carcinoma, an amebic granuloma was found. Both responded promptly to specific therapy. One should not forget the sad experience of the Chicago epidemic of 1933, when many patients with amebiasis were operated on in different localities under the erroneous diagnosis of other rectocolonic lesions, and usually with fatal results. Although the history is important, the results of a thorough examination are the decisive factors. Statistics indicate that about 10 per cent of patients with rectal carcinoma have been operated on or treated for internal hemorrhoids within the year prior to the date on which the correct diagnosis was made. In the majority of instances the tumor could have been felt or seen. The lesson is that no case of bleeding internal hemorrhoids should be treated palliatively, by injection or operation, before digital palpation and proctoscopy. There is a tendency to refer at once patients with rectocolonic symptoms for an x-ray examination before proctosigmoidoscopy. Clinical experience shows that the sequence should be reversed. It is well nigh impossible to demonstrate, by the x-rays, early lesions of the bowel within the bony pelvic girdle. Small tumors and ulcers are missed, and the nature of extensive ulcerative processes is not disclosed. It is not just to subject a patient to an x-ray examination for a lesion that can be felt or seen without the previous benefit of proctoscopy, nor is it fair to the roentgenologist who should be furnished with all the results of the proctologic examination before he undertakes the examination. By special study any general surgeon can

become proficient in proctoscopy. Failing this, the patient should have the benefit of an examination by one skilled in the use of the instruments and competent to interpret the character of the lesions seen and, when indicated, obtain directly material for smears and culture and representative biopsy specimens. This naturally leads to my major plea, namely, that every general hospital should have on its staff a competent proctologist supplied with the necessary instruments. The American Proctologic Society is performing a valuable service in disseminating knowledge in this special field to the profession in general, and in particular to those physicians who are devoting their time and effort to the specialty.

DURATION OF IMMUNITY AGAINST DIPHTHERIA ACHIEVED BY VARIOUS METHODS

WILLIAM HALLOCK PARK, M.D.

NEW YORK

Diphtheria toxin-antitoxin as an active immunizing agent was discovered in 1913 by Behring and became generally used in the United States from 1914 on. It was found to give immunity to 85 per cent of the subjects who received three 1 cc. injections, and the length of immunity from good preparations was determined by my co-workers and myself as being ten years or more in 80 per cent of the cases.¹

In 1924 Zingher and I² accepted the superiority of Ramon's anatoxin—or, as it is called in this country, the formol toxoid—as compared with toxin-antitoxin. We summed up this superiority by stating that toxoid is (1) more stable, (2) easier to prepare, (3) not dangerous if accidentally frozen, (4) more effective and (5) nonsensitizing. After 1931 administration of toxoid, in two or three doses, gradually supplanted the use of toxin-antitoxin both in Europe and in this country. The immunity achieved with two doses was usually 95 per cent, and the duration of immunity was assumed to be as long as with toxin-antitoxin. In 1931 Glenny and Barr³ described the alum-precipitated toxoid, which in single doses furnished as high immunity as the fluid toxoid did in two or three doses. The rapidity of the development of the immunity was also greater. Because of the convenience of the single injection, the use of alum-precipitated toxoid supplanted the use of fluid toxoid very rapidly, and from 1932 on, especially in the United States, this was the generally preferred method for immunization against diphtheria.

Recently several reports appeared in the literature which introduced some contradiction concerning the duration of the immunity when only one dose of alum-precipitated toxoid is used. The two best instances of such contradictory reports are those by Fraser from Canada⁴ and Farago from Hungary.⁵ Both used the accurate method of diphtheria antitoxin determination from the blood of immunized children.

Fraser started out with children who had less than $\frac{1}{600}$ unit of antitoxin per cubic centimeter in their blood. Thirty-five of these he immunized with three doses of fluid toxoid and forty with one dose of alum-

precipitated toxoid. Twelve months after immunization he found only 19 per cent of the children who had received one dose of alum-precipitated toxoid to have more than $\frac{1}{100}$ unit of antitoxin per cubic centimeter of blood, whereas 91 per cent of the children who had received three doses of fluid toxoid showed more than $\frac{1}{100}$ unit.

Farago's study leads one to different conclusions. He examined the blood of ninety-nine subjects who had received three doses of fluid toxoid and the blood of 102 who had received one dose of alum-precipitated toxoid two years prior to the investigation. Both from the point of view of the Schick tests and from the point of view of the antitoxin content of the blood, the children who had received only one dose of alum-precipitated toxoid did just as well as or better than the other group. Two years after immunization the incidence of positive reactions to the Schick test in the groups which had received three doses of fluid toxoid varied from 10 to 14 per cent and the average antitoxin content of the blood from 0.257 to 0.680 unit per cubic centimeter. On the other hand, the groups which had received one dose of alum-precipitated toxoid showed an average of from 0.562 to 0.567 unit of antitoxin per cubic centimeter of blood and a variation of from 4 to 11 per cent in the incidence of positive reactions to the Schick test. The interval between immunization and the determination of the antitoxin content of the blood and the Schick testing was two years in all the groups.

Farago's work combined twice as many cases and covered twice as long an interval between immunization and testing as Fraser's study. On the other hand, of his subjects, only those who received alum-precipitated toxoid had had a positive reaction to the Schick test before immunization. Three fourths of his patients had no initial Schick tests. Fraser's subjects were so selected that before immunization they all had less than $\frac{1}{100}$ unit of diphtheria antitoxin in their blood. Farago used fluid toxoid of 15 Lf per cubic centimeter and alum-precipitated toxoid of from 20 to 28 Lf per cubic centimeter. Fraser used 20 Lf potency for both the fluid and the alum-precipitated toxoid. Therefore, as a whole, Fraser's study, though covering fewer cases than Farago's, was more reliably set up.

Because of such contradictions in the literature about the value of different immunizing agents against diphtheria, a study concerning the duration of immunization against diphtheria was started in New York City. The results are not final yet, therefore, I am going only to touch on them.

The animal work—guinea-pigs being used for the study—was started about a year ago by Dr. Olga Povitzky in the Bureau of Laboratories of the City of New York Department of Health. One group received two or three doses of alum-precipitated toxoid, another group two or three doses of fluid toxoid and a third group one dose each of alum-precipitated and fluid toxoid. The last determination of antitoxin on most of the groups was done from forty-two to forty-six weeks after immunization. The poorest results were obtained on the group of guinea-pigs which received two or three doses of unmodified toxoid. The best results were obtained on the guinea-pigs which received the one dose of alum-precipitated toxoid followed by one dose of fluid toxoid. The group which was immunized with one, two or three doses of alum-precipitated toxoid alone gave results in between the other two groups. In the groups in which one, two or three doses

of either unmodified or alum-precipitated toxoid were given, three doses gave better results than two and two doses better than one

Interesting as Dr Povitzky's work is, it cannot be considered final, for the following reasons 1 The groups were small An average of only five guinea-pigs was used in each group 2 The last testing occurred only ten and a half months after immunization, and one can hardly study length of immunity in a group of animals observed for such a short time 3 Dr Povitzky pooled the blood of each group and tested the combination instead of the blood of each animal individually By this method the dispersion of the individual variations cannot be studied 4 In some of the groups to be compared, not only the type of toxoid used but the size of the doses differed

Dr Povitzky intends to continue to test these groups of guinea-pigs, if they live, for a second year and also to set up another and better planned experiment which

test, as against only 86 per cent of those immunized with two doses of unmodified toxoid The determination of antitoxin in the blood showed that one dose of alum-precipitated toxoid gave the highest antitoxin titer—about four times higher than that given by two doses of fluid toxoid I fully realize that because the time between immunization and the present study was about one year shorter for the group which received one dose of alum-precipitated toxoid than for the two other groups, the real superiority of alum-precipitated toxoid over the other preparations would be somewhat less than these figures suggest In table 2, three other factors are included on the right hand side which might have had an influence on the outcome of the study 1 The average age of the children when immunization occurred The three groups were fairly comparable in this respect 2 Previous immunization This is known to make it easier to effect subsequent immunization In this respect the group which received two doses of

will escape the weaknesses I have just pointed out in the original one

One piece of work on children which gives a comparison of the three commonly used methods of immunization against diphtheria was undertaken by Dr Camille Kereszturi in the Medical Center of Columbia University This is a small but very careful study and I should therefore like to discuss it in detail

Three groups of children were selected for study who were previously immunized as follows Twenty-one children were given three 1 cc doses of toxin-antitoxin, twenty-two children were given two 1 cc doses of unmodified toxoid, and twenty-one children were given one 1 cc dose of alum-precipitated toxoid All these sixty-four children had positive reactions to the Schick test before immunization The final Schick tests were given to the three groups, respectively, thirty-nine, thirty-seven and twenty-seven months after their last immunization The diphtheria antitoxin content of their blood was determined simultaneously with the last Schick test by Mr Charles K Greenwald in the Research Laboratories of the Department of Health It was found that 95 per cent of the children immunized with three doses of toxin-antitoxin or with one dose of alum-precipitated toxoid had negative reactions to the Schick

toxoid had the most advantageous position and the toxin-antitoxin group the least 3 Repeated Schick tests are known to produce a slight additional immunity, therefore, in the last column the incidence of interval Schick tests is charted From this point of view the group which received one dose of alum-precipitated toxoid had the most and the group which received two doses of unmodified toxoid the least advantage

Analyzing these factors which might influence the results, one has the impression that the one dose of alum-precipitated toxoid gives just as good antitoxin immunity against diphtheria as three doses of toxin-antitoxin or two doses of fluid toxoid Dr Kereszturi feels, however, that she wants to do the Schick test on a larger group of children to see whether the apparent superiority of the one dose of alum-precipitated toxoid is not due to chance because of the small number of cases For her next group she plans to choose children immunized with alum-precipitated toxoid prepared by the City of New York Department of Health rather than by any commercial laboratories As in her study the fluid toxoid used was a city product, with a potency of from 8 to 11 Lf per cubic centimeter, and the alum-precipitated toxoid was a commercial product of from 16 to 22 Lf per cubic centimeter, there is a chance that these differences influenced the outcome of the study

As far as I know, Dr Julius Blum and Dr M C Schroeder of the City of New York Bureau of Laboratories have the largest number of children with an initial positive reaction to the Schick test who have been immunized and afterward given another Schick test. Even their cases, however, are too few to give statistically significant results. The interval between immunization and final Schick tests furthermore, is too short to allow one to draw reliable conclusions as to the duration of the immunity against diphtheria. From table 3 it can be seen that Dr Blum obtained a positive reaction to the Schick test from one to two years after immunization with one dose of 1 cc of alum-precipitated toxoid in 40 per cent of his cases, as against 23 per cent in Dr Schroeder's series. Between two and three years after immunization the difference between the results of Dr Blum and those of Dr Schroeder was even greater, the figures being 82 per cent and 14 per cent. These two investigators used alum-precipitated toxoid prepared by the city and ranging in potency from $8\frac{1}{2}$ to 40 Lf per cubic centimeter.

Dr Blum's series of patients immunized, respectively, by two doses of unmodified toxoid and by three doses of toxin-antitoxin are even smaller. According to his data it appears that the immunity achieved by these two methods is more permanent than that given by the use of one dose of alum-precipitated toxoid. Between two and three years after immunization, only 4 per cent of the patients immunized with toxin-antitoxin and none of those immunized with two doses of fluid toxoid had positive reactions to the Schick test.

There is a tremendous difference between the results of Dr Blum's work and those of Dr Schroeder's. There is an even greater difference between the work of Dr Blum and that of Dr Kereszturi. I do not feel

2 The individual doses of toxin-antitoxin, unmodified toxoid and alum-precipitated toxoid should be the same.

3 The total number of injections with all three products should be the same.

4 The potency of the toxoid to be alum precipitated should be identical with that of the unmodified toxoid.

TABLE 3—Duration of Diphtheria Immunity Produced by Various Methods in Initially Schick Positive Children

	Interval Between Immunization and Schick Test in Years	Dr Blum			Dr Schroeder		
		Total	Number Positive Schick	Per Cent Positive Schick	Total	Number Positive Schick	Per Cent Positive Schick
3 x 1 cc toxin-antitoxin	$1\frac{1}{2}$ 1						
	1 2	39	3	8			
	2 3	72	3	4			
2 x 1 cc fluid toxoid	$\frac{1}{2}$ 1						
	1 2	66	0	7			
	2 3	20	0	0			
1 x 1 cc alum precipitated toxoid	$\frac{1}{2}$ 1				66	12	18
	1 2	13	54	40	103	24	23
	2 3	63	52	82	29	4	14

5 The ages of the children to be immunized should be similar.

6 The Schick testing should be done equally frequently for each group.

7 The length of the experiment should be equal for all three groups and should be five years or more.

8 The number of cases in each group should be large enough to render the conclusions statistically significant.

None of the work done either in this country or elsewhere even approximates these conditions. I am therefore very hesitant to draw conclusions at present about the comparative duration of immunity against diphtheria gained by different methods. While the necessary material is being collected for a more conclusive study, I think the Department of Health of the City of New York is wise to be conservative and go back to a standard of two doses of toxoid, either fluid or alum precipitated.

SUMMARY

1 There is a great deal of controversy in the literature concerning the best method of immunization against diphtheria from the point of view of duration of the immunity achieved.

2 None of the material available at present on this subject is suitable for the deriving of statistically valid conclusions.

3 A small but I believe very important piece of work done on animals by Dr Povitzky suggests that the best results with two doses might be obtained by the use of a 1 cc dose of alum-precipitated toxoid followed by a 1 cc dose of fluid toxoid.

4 Pending conclusive determination of the best method of immunization against diphtheria, the administration of two or three doses of either fluid or alum-precipitated toxoid is the wisest procedure.

Park Laboratory, Department of Health

ABSTRACT OF DISCUSSION

DR. M. BERNARD BRAHDY, Mount Vernon, N. Y. Dr. Park has shown that two doses of toxoid give a more lasting immunity than one dose of precipitated toxoid. Whenever possible, multiple dose immunization should be the procedure of choice. The results that we obtained in the parochial schools of Mount Vernon substantiate those presented by Dr. Park. Schick tests were done in a group of 225 children in the lower grades who

Standard deviation 3.0

prepared to pass any judgment on the results arrived at by these three workers, both because the number of cases dealt with by them is too small to be statistically valid and because the preparations used differed widely in potency. I am convinced that the final answer to the problem of the duration of immunity against diphtheria achieved by various methods cannot be found reliably unless a long time special experiment is set up for this purpose.

Such an experiment, I believe, would have to conform with the following specifications:

1 Only children with an initially positive reaction to the Schick test should be used.

had received three doses of toxin-antitoxin from three to nine years before and 83 per cent were negative. After six months 95 per cent were Schick negative. However, in the children given Schick tests after an interval of a year, 10 per cent of those who had been Schick negative became positive. I wish to emphasize a point frequently overlooked in determining the efficacy of a one dose method of immunization, and that is whether the child had a previous injection of diphtheria antigen. Several years ago Fraser by his work in Toronto demonstrated the importance of knowing whether antitoxin is present in the serum before injecting an antigen, when attempting to determine the immunizing power of that antigen. We had less success than Dr. Park with the use of two doses of fluid toxoid, although we used only 0.5 cc per dose. A group of 110 children of school age who were tested from two to three years after the injections showed an immunity of only 78 per cent. This low figure is in agreement with that reported by Cooke, who recently found 77 per cent immunity in a group of nurses a short time after injection of two doses of 0.5 cc of fluid toxoid. I believe that 0.5 cc of fluid toxoid is too small a dose. Reactions occur more frequently after injections of toxoid than after toxin-antitoxin. It was thought that the intradermal toxoid skin test or Moloney test would indicate those children who would have reactions. Dr. Hayman has correlated the data on the Moloney test and reactions to toxoid injections in 528 children at the Willard Parker Hospital. In children under 4 years of age with a positive skin test (15 per cent) there was usually no reaction following the subcutaneous or intramuscular injection of toxoid. However, in the older age groups either local or general reactions occurred in from 30 to 60 per cent of those with positive Moloney tests (50 per cent). Among those with negative Moloney tests only 6 per cent had reactions after the injection of toxoid. There are certain lessons in Dr. Park's paper which we should carry home. We must not sacrifice efficacy for simplicity—one dose of antigen is a simple but not an effective method of immunization. Until we have a method of immunization which will give a more lasting immunity in most of our children, it is important for us to perform repeated Schick tests. Schick tests should be repeated every few years or at least when we do our preschool medical examination.

DR. JULIUS BLUM, New York. As a co-worker of Dr. Park's, I agree with everything he has said. I wish, however, to emphasize my experiences with alum precipitated toxoid and fluid toxoid for the past few years. The introduction of alum precipitated toxoid by Glenn in England in 1930 and by Havens of the U. S. Public Health Service in 1932 in this country was hailed as the ideal antigen in the active immunization against diphtheria, because only one injection of 1 cc was sufficient to give immunity in 95 per cent or more cases in the comparatively short period of one month. The disadvantages were a nodule, persisting at the site of inoculation, for as long as three months, and occasional abscess formation. The persistence or loss of immunity following this method of immunization was not questioned until Fraser and Halpern published their results in the *Canadian Public Health Journal* for October 1935. These observers found that after one year only 19 per cent of the one dose alum group remained above the $\frac{1}{400}$ level of antitoxin, whereas 91 per cent of the three dose unmodified toxoid group remained above that level. These surprising results led us to give Schick tests to all children who had been immunized with one dose of alum precipitated toxoid. As shown by Dr. Park, in 239 Schick positive children who were immunized with one dose of 1 cc of alum precipitated toxoid, with various preparations containing flocculating values of from 85 to 40 units per cubic centimeter, 26 per cent lost their immunity in nine months, 40 per cent in from one to two years and 82 per cent in from two to three years after inoculation. In 103 children who received two injections of unmodified fluid toxoid of 1 cc. each two weeks apart there was no loss in immunity in seventeen cases at nine months, in 75 per cent in sixty-six cases at from one to two years and no loss in twenty cases at from two to three years. The importance of these observations should be stressed. As a public health measure it is advisable therefore until further data are obtained, that unmodified toxoid be used in immunization against diphtheria. It is advisable that Schick tests be performed on all children

who have received one dose of alum precipitated toxoid and to reimmunize all positive reactors. It is also possible that this loss of immunity may be a factor in the explanation of the increased incidence and the increase in mortality from diphtheria in the first five months of 1937 in the city of New York, where alum precipitated toxoid has been commonly used in the past few years. Until the third week in May during 1937 there were thirty-one deaths from diphtheria in the city of New York, compared to a total of thirty-six for the year 1936.

DR. MAX SCHRODER, New York. I should like to ask Dr. Blum whether all the patients who died of diphtheria in the first half of 1937 had been investigated and found to have received one dose of alum precipitated toxoid.

DR. JULIUS BLUM, New York. I cannot answer that question. These results were published about two weeks ago. I am tolerably sure that the thirty-one deaths did not all occur in persons who were previously injected with alum precipitated toxoid. I do, however, know this: a friend of mine had two cases of diphtheria in his own private practice occurring from one to two years after the administration of alum precipitated toxoid.

DR. WILLIAM H. PARK, New York. The second dose is very effective in that it continues the immunity developed by the first dose. Two doses are much more effective than one dose. I believe that the toxoid precipitate is a better immunizing agent than is the fluid toxoid. However, both are good. I think that in every case the physician should use two doses either of the precipitate or of the fluid toxoid. I hope that every one will retest the children a year after the first immunization to note the results.

OVARIAN FIBROMA WITH ASCITES AND HYDROTHORAX (MEIGS'S SYNDROME)

REPORT OF A CASE

J. E. RHOADS, M.D.

AND

ALEXANDER W. TERRELL, M.D.

(PHILADELPHIA)

Fibroma of the ovary, an uncommon tumor, may rarely be associated with hydrothorax as well as with ascites. The knowledge that this association of pleural effusion with a benign pelvic tumor exists is extremely important from the standpoint both of prognosis and of treatment, since most pelvic tumors causing pleural effusion are malignant and the effusion is the result of pleural or pulmonary metastasis. In the presence of massive pleural effusion it may at times be impossible, even after partial aspiration, to exclude the presence of pulmonary metastasis by x-ray examination. We feel, then, that in these instances the occurrence of hydrothorax with a pelvic tumor justifies abdominal exploration and promises substantial hope of recovery in a considerable group in which the prognosis was previously regarded as hopeless.

Recently Meigs and Cass¹ reported a series of seven cases presenting the syndrome of fluid in the chest in association with ovarian fibroma. In most instances symptoms referable to the chest (shortness of breath or discomfort and pain in the chest) were the chief complaints. In every case the hydrothorax disappeared following removal of the ovarian tumor. Although cases of fibroma of the ovary had previously

been recorded in the literature and hydrothorax accompanying this tumor had been mentioned (Hoon,² Salmon,³ Leo,⁴ Meigs⁵), their occurrence and the clinical picture of hydrothorax, which is at times associated with their presence, is not generally recognized. It is Meigs and Cass's article that first reports this syndrome completely and emphasizes its significance.

The importance of recognizing this condition is exemplified by the following case, admitted to the

Fig 1—Massive pleural effusion in right side of chest one day after the first thoracentesis. 1 900 cc of fluid had been removed.

hospital at the time the report of Meigs and Cass¹ appeared and in which a tentative diagnosis of sarcoma of the uterus with metastasis was first made.

REPORT OF CASE

History—E. P., a white woman, aged 57, a widow, admitted to the University of Pennsylvania in the service of Dr. Alfred Stengel Feb. 1, 1937, complained of shortness of breath, fatigue and the loss of 18 per cent of her body weight.

never observed any peripheral edema. There were no digestive symptoms except for moderate anorexia and belching. She had never had any abdominal pain nor had she ever complained of abdominal fullness or distention.

The menopause occurred at the age of 53, four years before the present admission. The menses had begun at 15 and had always been regular. She had had three normal pregnancies. There had been no postmenopausal bleeding or discharge. For many years the patient had been under the care of a physician who had noted a large pelvic tumor in the median line at least eight years previous to her admission, which had not grown appreciably during the interval.

On the admission of the patient to the hospital the temperature was 98 F, pulse rate 90, respiratory rate 20 and blood pressure 130 systolic 85 diastolic. The patient was thin and rather cachectic looking and was prematurely aged. She was myopic and moderately deaf. Examination of the chest revealed signs of massive pleural effusion on the right side. The trachea was deviated somewhat to the left and the apex of the heart was displaced toward the left. There were no other abnormal physical signs in the left side of the chest. All these observations were confirmed by x-ray examination (fig. 1). Abdominal examination indicated the presence of

Fig 2—Appearance seven weeks after operation. No thoracentesis was performed during this time. A small amount of fluid was still present.

Summary of Nine Cases in Literature in Which Hydrothorax Was Associated with Ovarian Fibroma

Case	Author	Age, years	Status	Chief Complaints	Location of		Thoracentesis Number	End Result	Comment
					Tumor	Pleural Effusion			
1	Meigs and Cass ¹	42	Single	Pain in right chest, dyspnea, cough	Right ovary	Right	0	Good	Had two preoperative abdominal paracenteses; considerable amount of ascitic fluid at operation.
2	Meigs and Cass ¹	51	Married	Pain in right chest, cough, abdominal discomfort	Right ovary	Right	5	Good	From six to eight quarts of ascitic fluid found at operation.
3	Meigs and Cass ¹	38	Married	Pain in left chest, abdominal discomfort, dyspnea	Left ovary	Left	5	Good	Five abdominal paracenteses; several quarts of ascitic fluid at operation.
4	Hoon ²	36	Married	Abdominal bloating, anorexia, loss of weight and strength	Right ovary	Bilateral	1	Good	Marked ascites at operation.
5	Hoon ²	31	Married	Abdominal pain and bloating, dyspnea	Right ovary	Right	1	Good	One abdominal paracentesis; several liters of ascitic fluid present at operation.
6	Leo ⁴	64	?	Pain in right chest, dyspnea, cough	Left ovary	Right	Repeated chest taps necessary	Good	Large amount of ascitic fluid at operation.
7	Meigs and Cass ¹	51	Single	Dyspnea, change in bowel habits, weakness	Left ovary	Right	1	Good	A large amount of ascitic fluid at operation.
8	Salmon ³	52	Married	Lower abdominal cramps	Right ovary	Right	1	Good	700 cc of ascitic fluid in abdomen.
9	Rhoads and Terrell	50	Married	Dyspnea, fatigue, weight loss, cough	Right ovary	Right	2	Good	See report of case.

When she became dyspneic a dry cough developed but she had never had hemoptysis or pain in the chest. Palpitation had been noted during attacks of dyspnea and fatigue. She had

a small amount of ascites. In the right upper quadrant the liver was palpable three fingerbreadths below the costal margin. A large round firm tumor extended from the pelvis to a point midway between the symphysis pubis and the umbilicus. On pelvic examination this appeared to be attached to the cervix and was firm, freely movable with the uterus and not tender. The pelvic mass prevented satisfactory palpation of the adnexa. There were no nodules felt in the cul-de-sac. Aside from arthritic changes in the fingers and the finding that the right pupil was smaller than the left, there were no

other important physical signs. Because of the ascites and hydrothorax a tentative diagnosis of uterine sarcoma with metastases was made.

Thoracentesis was performed five times and fluid was removed from the right pleural cavity as follows: February 2, 1,900 cc.; February 5, 1,000 cc.; February 10, 3,000 cc.; February 19, 2,000 cc.; and March 3, 1,000 cc. After the third thoracentesis, with removal of 3,000 cc. of fluid 1,500 cc.

Fig. 3—Cut surface of fibroma of right ovary

of air was injected in an attempt to get better x-ray visualization of the pleura and right lung field. Within nine days x-ray examination of the chest showed reaccumulation of a large amount of fluid. So rapid was this reaccumulation that there was a large mediastinal herniation containing both air and fluid and extending to the midportion of the left lung field. This necessitated removal of 2,000 cc. of fluid, for relief of the dyspnea.

The laboratory data obtained in this case may be summarized as follows: Blood count on admission: red blood cells 5,500,000; white blood cells 18,200; hemoglobin 98 per cent. The differential count was: polymorphonuclear cells 75 per cent, lymphocytes 22 per cent, monocytes 2 per cent, eosinophils 1 per cent. Subsequent blood counts never disclosed a leukocytosis. Repeated urinalyses showed a specific gravity varying from 1.012 to 1.027, an occasional trace of albumin and a moderate number of white blood cells. The Kolmer and Kahn tests were negative for syphilis. The urea nitrogen content of the blood was 15 mg. per hundred cubic centimeters and the blood sugar 78 mg. per hundred cubic centimeters. Serum protein was 6.9 Gm. per hundred cubic centimeters on admission. The sedimentation rate was 22 mm. in sixty minutes.

The pleural fluid obtained February 2 showed a specific gravity of 1.021. It contained 450 cells per cubic millimeter (96 per cent mononuclear and 4 per cent polymorphonuclear) and 1.75 Gm. of protein per liter. February 5 fluid with similar specific gravity showed, on long centrifugation, only an occasional normal red blood cell and a few lymphocytes and polymorphonuclear cells. No mitotic cells were found. None of the cells appeared malignant. February 19 the specific gravity was 1.014, the protein was 1 Gm. per liter and the cell count was 514 cells with 86 per cent mononuclear and 14 per cent polymorphonuclear cells. Cultures of the fluid were repeatedly negative. Guinea-pig inoculation was done on two occasions but tuberculosis did not develop in the animals.

Because numerous x-ray examinations following injections of air did not show the expected pleural or pulmonary metastatic lesion thoracotomy was considered. It did not offer the patient much prospect of benefit, however. At this time the gynecologic consultant, Dr. Franklin Payne, suggested

that the pelvic tumor could be an ovarian fibroma, as in the syndrome just described by Meigs and Cass.¹

Accordingly, March 4 the patient was transferred to the surgical division and exploratory laparotomy was performed by Dr. I. S. Ravdin. A moderate amount, probably in excess of 750 cc., of ascitic fluid was found. The pelvic mass proved to be a tumor of the right ovary measuring 14 by 10.5 by 10 cm. (fig. 2). It was readily removed. Exploration of the remainder of the peritoneal cavity showed no abnormalities. Convalescence from operation was smooth and uneventful. The last pleural aspiration was done on the day before operation, when 1,000 cc. of fluid was removed.

X-ray films of the chest taken on the sixth and fifteenth postoperative days showed progressive diminution in the pleural effusion and reexpansion of the right lung. The patient did not require thoracentesis following the operation. At the time of discharge, March 23, the blood count was entirely normal, the serum protein was 7.3 Gm. per hundred cubic centimeters and the patient was subjectively cured and objectively improved.

Follow-up examination was made April 22, seven weeks following operation. The patient was feeling very well, an excellent appetite had replaced the anorexia, she had no symptoms of breathlessness, cough or fatigue, and she had gained weight. Physical examination was negative except for the signs of a very small amount of fluid or thickened pleura at the right base. X-ray examination at this time showed great

Fig. 4—Section of the tumor ($\times 160$). The smooth muscle appears black in the photomicrograph (Masson stain).

improvement in the appearance of the right lung field. The entire right lung had reexpanded and there was only a small amount of fluid above the dome of the diaphragm. The pleura appeared somewhat thickened (fig. 3).

Pathologic Examination.—The tumor weighed 810 Gm. It was rounded and smooth. The surface was traversed by

few moderately large vessels. The consistency was firm, approximately that of a squash ball. The tumor appeared to be a diffuse enlargement of the ovary. On section (fig 3) the tumor showed whorls of fibrous tissue such as those often seen in uterine fibromyomas. No cystic areas were found. The tumor was hardened in solution of formaldehyde. Sections were cut at right angles to the surface and stained with hematoxylin and eosin. The tumor appeared to be composed of fibrous tissue with numerous fibroblasts. This was interspersed in every low power field with eosin staining areas having the appearance of smooth muscle. The Masson stain, which colors fibroblasts purple and muscle cells green, definitely established the presence of both elements (fig 4). The pathologic diagnosis was stromatogenous fibromyoma of the ovary.

COMMENT

From recorded reports one must judge that fibroma of the ovary is an infrequent tumor. Its incidence is estimated at from 2 to 2.5 per cent of all ovarian tumors (Hoon,² Lynch and Maxwell⁶). It has been reported at ages ranging from 8 to 83 but is quite rare under 25 years and usually occurs between the ages of 30 and 50. It is bilateral in about 20 per cent of the cases, according to Lynch and Maxwell, and, if bilateral, amenorrhea and sterility are usually present. The tumor has been associated with ascites in 40 per cent of Peterson's⁷ eighty-four collected cases, in 25 per cent of Hoon's² series and in only 13.7 per cent of Meigs's⁵ series of twenty-nine cases from the Massachusetts General Hospital. Cachexia is said to be commonly associated with large ovarian fibromas. The largest on record measured 35 by 23 by 15 cm and weighed 6,023 Gm. It was reported by Hoon.² There are only nine cases in which an associated hydrothorax has been reported.

The accompanying table outlines the age, marital status, chief complaint, location of tumor, location of hydrothorax, number of thoracenteses and end results in each case. As in our patient, several of the reported tumors were palpated in the midline. It should be noted that in our patient and in other reported cases the amount of fluid in the chest exceeded the amount of ascitic fluid.

The uniformly good results following removal of the fibroma indicate an etiologic relationship between the tumor and the ascites and hydrothorax. The mechanism of this relationship is not known. Several explanations of the ascites associated with ovarian fibromas seem plausible, but no explanation of the hydrothorax has as yet been afforded.

The Shut-In Personality—The type of personality make-up which is particularly in danger of developing into the disease processes of dementia praecox has been described by Hoch as the shut-in personality. We find, in dementia praecox persons who do not have a natural tendency to be open and get into contact with the environment, who are reticent, seclusive who cannot adapt themselves to situations, who are hard to influence, often sensitive and stubborn, but the latter more in a passive than in an active way. They show little interest in what goes on, often do not participate in the pleasures, cares and pursuits of those about them, although often sensitive; they do not let others know what their conflicts are; they do not unburden their minds; are shy, and have a tendency to live in a world of faunias.—Michele Pompeo. *Dementia Praecox*. *Preventable Psychiatric Quart* 11:552 (Oct) 1937.

THE SURGICAL TREATMENT OF
UTERINE MYOMAS

VIRGIL S. COUNSELLER, M.D.

ROCHESTER, MINN.

The mortality in pelvic operations is definitely lower than it is in other types of abdominal operations when the usual surgical principles and standardized techniques are employed, thus, the surgeon may not feel the same degree of hesitancy in undertaking pelvic operations as he does, for instance, in undertaking operations on the upper portion of the abdomen. For these reasons pelvic operations are often performed when there is only the slightest indication for them and at times when there is no real indication at all. It should be remembered that the mortality attending any operation reaches its maximum in the hands of inept or insufficiently trained men.

Although benign lesions of the uterus rarely are difficult to eradicate, there are conflicting ideas regarding the best procedure to follow. I refer principally to the treatment of myomas, which occupy unusual positions with respect to the uterus.

Myomas are most frequently encountered between the ages of 25 and 45 years, the greatest number which require treatment occur after 35 years and the highest

Fig. 1—Huge interligamentous fibroid originating from the left side of the uterus near the internal os; it completely filled the left broad ligament and pelvis and produced marked distortion of the left ureter; there is an absence of myomas in the remaining portion of the uterus.

incidence is at 45 years of age. It is said that after the age of 35 years 20 per cent of all women have some type of myoma. Not all of these will require treatment, however. Myomas do not, as a rule, grow after the menopause but surgical treatment will be required in many cases as a result of degenerative changes.

Some of the fundamental points to keep in mind in undertaking treatment of myomas are their blood supply, their cleavage planes and their manner of growth. Generally speaking, myomas of all sizes are practically devoid of blood vessels. They obtain their blood supply from a thin capillary network from the vessels of the myometrium. For this reason, operation can be undertaken with practically no fear of troublesome hemorrhage. However, this rule does not hold for large pedunculated tumors that have a large pedicle, for the pedicle is usually extremely vascular and large tumors may be soft and filled with excessive amounts of blood, so that retrograde bleeding from the tumor may be severe. When this condition is encountered, much blood, which is valuable to those who are anemic as a

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.

result of repeated hemorrhages may be put back into the circulation immediately by injecting from 1 to 2 cc of solution of posterior pituitary into the tumor before its pedicle is clamped. I have encountered myomas in which the pulsations could actually be palpated in the pedicle of the tumor.

Tumors that are growing in the myometrium compress the musculature of the uterus around the tumor and have the appearance of being encapsulated. The

Fig. 2—Unusual arrangement of myomas which have almost completely destroyed the uterine mucosa; the contour of the peritoneal surface of the uterus is normal.

tumor, which is much firmer than the myometrium can be readily enucleated when the cleavage plane between the tumor and the myometrium is entered. This is best accomplished by holding the tumor firmly with one hand and incising through the myometrium directly down to the tumor. The tumor then is visible and the plane of cleavage can be readily entered. The capillary blood vessels of the capsule can be best controlled by pressure until the defect in the myometrium is closed by a continuous mattress suture. The line of cleavage in myomas clearly distinguishes them from the adenomyomas, since the latter are intimately fused with musculature of the uterus.

The situation of the myoma in relation to the uterus is highly important in selecting the type of surgical treatment. The greater proportion of the tumors are situated in the body of the uterus usually on the anterior or posterior wall. They are usually designated as subserous, interstitial or submucous, according to whether they are under the peritoneum, embedded in the wall of the uterus or under the mucosa. It is considered that they all originate within the myometrium and later extend toward the surface of the uterus or toward the uterine cavity. The question of the direction of extension that any of these tumors take may have a very decided influence on their removal. For instance, those that grow toward the peritoneal cavity may remain on the surface of the uterus or become pedunculated and offer no serious difficulty to their removal, but those which happen to grow from the lower portion of the uterus may extend laterally into the broad ligaments under the bladder or posteriorly behind the peritoneum of the culdesac of Douglas. In the cellular tissues of the broad ligament the tumor may grow without interruption; it may retain its connection to the uterus or it may become completely separated from the uterus. Since the uterine vessels enter the uterus near the internal os and since the most fixed point in the entire course of the ureter from the kidney to the bladder is closely associated with the tumor at this point these structures are pushed laterally during the growth of the tumor and may present real difficulties during the surgical extirpation of such

tumors (fig. 1). It is frequently in connection with the removal of an interligamentous myoma that the ureter is injured. The veins often are enlarged from pressure and under tension resemble a ureter when it is free from blood. There is one maneuver which, if carried out at this point, will definitely determine whether one is handling the ureter or not. If the ureter is snipped or otherwise irritated with the thumb forceps, it forcibly contracts, this distinguishes it from blood vessels. Any attempt to remove a large myoma in this situation without adequate exposure and without opening the broad ligament wide so that important structures can be readily seen, will result in trouble, some hemorrhage and perhaps injury to the ureter and bladder. It has always been my custom to open the broad ligament posteriorly, and then identify and retract the ureter at once so that any troublesome hemorrhage can be immediately controlled without fear of injury to the ureter. The necessity for determining the position of the ureter and protecting it from injury is further enhanced by the fact that it may be the only functioning ureter that the patient has left. The other ureter may be congenitally absent or may have been destroyed by disease or by pressure in the broad ligament, or it may have been injured in a previous pelvic operation. The discovery of a ureter which has been destroyed by a previous pelvic procedure is not at all uncommon.

A myoma that extends from the posterior wall of the uterus far down behind the peritoneum of the culdesac of Douglas is one that presents several technical difficulties in its removal. Again the ureters are both pushed laterally, and the tumor grows upward in the mesentery of the sigmoid colon and the cecum. It is usually this type of myoma that is occasionally exposed and considered inoperable, the patient is then subjected to radium or roentgen therapy. If exposure is adequate and the condition thoroughly recognized, the tumor can be removed by careful dissection after retraction

Fig. 3—Pedunculated myoma with pedicle attached to the fundus; the cervix is large and patulous and the site of ulceration stained at necropsy.

of the blood vessels in the fat of the mesentery of the colon. The safest method is to begin the removal by cutting through the peritoneum near the point of origin of the tumor and working laterally, always keeping in intimate contact with the wall of the tumor.

A myoma that originates from the anterior uterine wall near the cervix may cause considerable distortion of the bladder. It has been my experience that

the posterior wall of the bladder is often intimately attached to the fascial tissues adjacent to the fibroid which interferes with the separation of the bladder. If in separating the bladder the wall of this organ is injured, it is a much safer procedure to resect the wall of the bladder, leave it attached to the myoma, and then close the bladder with two rows of number 1 plain

Fig 4—Diagrammatic sketch of cervical myoma in a young woman whose pelvic organs were otherwise normal

catgut sutures. This may seem like a major procedure, but it is far safer than to run the risk of the development of a vesical fistula in a few days, as a result of the injury of the vesical wall or a persistent cystitis, which often follows extensive trauma, or to run the risk of the occurrence of secondary hemorrhages within the mucosa of the bladder.

Myomas that grow toward the uterine cavity form a distinct group and their surgical management is therefore different. As they extend toward the uterine cavity they become fixed beneath the mucosa, therefore they have been called "submucosal myomas" (fig 2). Some maintain this position, while others, on account of contraction of the uterine wall and the growth of the tumor, become pedunculated and extend at varying distances through the cervical canal. The submucous myoma is frequently troublesome and difficult to identify. Bimanual examination will perhaps show a normal contour of the uterus, although the organ may be somewhat larger than normal. If the tumor is small it is only after great care that it is identified with the curet. I am convinced that such tumors are often overlooked, if so, the excessive menorrhagia and metrorrhagia continue as they did before. Such patients too often are given a castrating dose of radium or roentgen rays. If the patient is already in the menopause this treatment may be adequate and proper, but continued spotting and frank hemorrhage not infrequently follow such treatment. In cases in which the patients are less than 40 years of age, these myomas should be removed surgically. Two methods are available. First if the cervix is thoroughly dilated the tumor may be grasped with a tenaculum, and then with one hand on the fundus to hold it in position the tumor may be extracted from the uterine wall by careful rotation and gentle traction. Subsequent bleeding is rarely of major importance and is usually controlled by packing

the uterus with gauze for from twenty-four to forty-eight hours. Second, if this maneuver is unsuccessful, the myoma should be removed by abdominal myomectomy and always by the latter procedure if there are other myomas in the myometrium or subserous myomas, which also should be removed.

Pedunculated submucous myomas behave exactly as does a foreign body in the uterine cavity. As the tumor increases in size the uterus endeavors to expel it, the same as it does a large blood clot. There is often a disturbance of the blood supply of the uterus, which favors necrosis, secondary infection and softening. The cervix then becomes soft, enlarged, patulous and inflamed (fig 3). If the pedicle becomes sufficiently elongated the myoma may be extruded into the vagina, where it undergoes ulceration, and bleeding is often of a serious nature. The vaginal discharge becomes excessive and the odor resembles that of an ulcerating carcinoma of the cervix, for which the myoma may be easily mistaken. Vaginal myomectomy is the only procedure ever to be employed in the removal of such myomas. If the patient is a woman who has been pregnant, adequate exposure is always possible, but if she is a nullipara it may be necessary to secure exposure by deep lateral episiotomy. The tumor should be grasped with the hand and not with instruments, for such tumors are soft, friable and hemorrhagic. The tumor may be gently pulled downward and the pedicle inspected. The cervix is often large and soft enough to permit one to examine the interior of the uterine cavity by inserting the index finger along the pedicle. The only other point which must be noted in the complete removal of such tumors is the union of the pedicle with the uterine wall. Should this be disregarded, an effort to remove all the pedicle may inadvertently result in an opening through the uterine fundus, which is also very soft. The point of attachment can usually be detected with good exposure and direct light. It is

Fig 5—Successful removal of the tumor with reattachment of a rim of cervical tissue to the uterus. menstrual function was normal

rarely necessary to ligate or suture the stump of the pedicle to control bleeding. Following removal of the tumor, the interior of the uterus should be cleansed with some antiseptic solution such as an aqueous solution of merthiolate or mercurochrome, or a weak solution of iodine. If bleeding seems excessive, packing with gauze is usually sufficient.

If these pedunculated myomas are associated with others which necessitate an abdominal hysterectomy,

this procedure must most emphatically be deferred several weeks until the cervix has assumed a normal consistency and the uterus is free from infection. It is decidedly dangerous to attempt a total abdominal hysterectomy when there is a pedunculated myoma extending into the vagina, since the tumor is always infected and peritonitis is almost certain to follow

Fig. 6—Myoma originating from the posterior lip of the cervix, the uterus which contained small myomas was situated on top of the cervical myoma near the umbilicus

The same is true if hysterectomy is attempted too soon following vaginal myomectomy, as the lymphatics will continue to contain streptococci, which may produce a fulminating peritonitis and death of the patient.

Cervical myomas, which fortunately are not common, present one of the most difficult surgical situations in gynecology. Their removal is necessary and always difficult on account of their position and the inherent danger of injuring adjacent structures. These tumors, according to Robert Mayer, are unlike the fundal myomas in that they are not influenced by the sex hormones and therefore do not undergo regression after the menopause. When excessive hemorrhages develop they are often treated by roentgen rays, on account of the technical difficulties presented in their surgical removal which as a rule is inadequate. Unlike the pedunculated myomas which protrude through the cervix they are not infected, therefore, surgical exploration can be instituted immediately. On account of their tendency to grow backward toward the culdesac of Douglas and upward, the abdominal type of hysterectomy is preferable. Although myomectomy is possible (figs. 4 and 5) if the fundus of the uterus is not involved by the myoma it will occupy a position on top of the tumor and usually will be situated near the umbilicus (fig. 6). The ureters, bladder and rectosigmoid must be carefully mobilized during the removal of the uterus.

Abdominal myomectomy, subtotal hysterectomy and total hysterectomy may also be considered in the treatment of myomas. The choice of any of these procedures depends on the size, number and situation of the tumors, on the age of the patient and on the con-

dition of the cervix. During the sexual life of the patient it is imperative to conserve both the menstrual and the reproductive function. Myomectomy is the only conservative procedure and the operation of choice in the third and fourth decades of life. When tumors are large and multiple myomectomy would result in considerable destruction of the uterus, myomectomy may best be replaced by hysterectomy if the patient is past 37 years of age. If hysterectomy is advisable before this period it is evidence that the patient has delayed seeking treatment or has been ill advised. In this connection it must be remembered that not all myomas will require surgical treatment, one or two small tumors, which occasionally are situated in the myometrium or in a subserous position, do not induce any disturbance in the menses and furthermore may become more or less quiescent and remain so throughout the patient's life. Such tumors will require periodic examinations to determine their size and consistency. In no event are these tumors to be treated by radium or roentgen rays during the sexual life of the patient. For such treatment to be effective it is necessary to administer a castrating dose, which is decidedly not indicated during this period of life. Some of the most dissatisfied patients are those who have received applications of radium, for bleeding due to myomas, when they were in their early thirties. In such cases the ovary usually regains some of its function and continuous spotting or excessive bleeding returns. Myomectomy, which must always be given consideration in cases in which removal of the tumors is indicated, is one of the most satisfactory operations in gynecology. However, it is more difficult to perform than subtotal hysterectomy, since the technic of the former is necessarily varied to suit the condition encountered. Bleeding need not deter the surgeon, as it can be adequately controlled if an assistant maintains gentle traction on the fundus

Fig. 7—Vaginal mucosa is inverted by running mattress suture and leaving the upper end of the vagina broad. Broad ligament are shortened and approximated with uterine vessels to the angles of vagina.

of the uterus during the operation. The removal of a degenerating myoma from the pregnant uterus is liable to interfere with normal labor and should not be considered lightly, although it can be done without much risk of miscarriage if extreme care is exercised. The contraction of the uterus from manipulation distinctly clearly the line of cleavage from the fibroid, since the myoma does not enter into the contraction to the same extent as does the uterus.

All large myomas and all small ones except submucous pedunculated myomas, which produce symptoms after the patient is 40 years of age, are best treated by the radical procedure of hysterectomy. Myomectomy may be considered if the patient prefers that the sexual organs be left intact. The operation of partial defundectomy has been advised in such cases but I do not consider it a satisfactory procedure.

Irradiation is often utilized in the treatment of some of the smaller fibroids, especially if it has been previously determined that they are incidental and not primarily the cause of the uterine bleeding. Irradiation at this period of life will be more likely to effect a cure than it will in the earlier years of life, since the recuperative power of the ovary has practically ended. Tumors of large size or those which increase in size or become tender following the menopause should be removed surgically. The same holds true for myomas that are associated with adnexal tumors or pelvic inflammatory disease.

The question of whether a subtotal or total hysterectomy should be performed when removal of the uterus is indicated for benign conditions should be determined by the condition of the cervix of the uterus. There is no more logic in leaving an infected, lacerated and eroded cervix when the uterine corpus is removed than there is to fail to extract an infected dental root which is a constant source of septic absorption into the general system. Neither is it logical to believe that total hysterectomy should always be done to prevent the occurrence of carcinoma on the retained cervical stump, since the incidence of such an occurrence is relatively small. It is rather generally agreed among gynecologists that the vagina is left in a more normal condition if a normal cervical stump is retained than it is if the cervix is removed. The cervix, of course, should be firm and free from cysts, lacerations and erosions. A cervix that meets all these requirements is not frequently found among multiparous women but is rather the rule among nulliparas. When a diseased cervical stump has been left following subtotal hysterectomy it should be destroyed by the surgical cautery. I prefer to remove it surgically by the vaginal route, as the convalescence is much shorter and infinitely more comfortable if it is removed in this manner.

When total hysterectomy is performed there is of necessity a greater disturbance in the function of the bladder, as some of the branches of the presacral nerve which supply the base of the bladder reach it by way of the uterosacral ligaments and pass around the cervix to reach the wall of the bladder. These nerves are divided when the uterosacral ligaments are severed. Furthermore, some dysfunction results from pushing the bladder away from the anterior wall of the uterine cervix. Several days are often required for the bladder to compensate for this dysfunction, which usually interferes with complete emptying of the bladder.

The support of the vaginal vault following total hysterectomy is a procedure of major importance. The discomfort which ensues from faulty support of the vaginal vault is intolerable and most difficult to remedy. As the vagina prolapses the bladder goes with it, this accounts for residual urine, infection and dragging and bearing down sensations. The condition is preventable if the pelvic fascia is accurately attached to the sides of the vagina. The other uterine ligaments are of minor importance in comparison to the fascia

within the broad ligaments (figs 7 and 8). Briefly, it is sufficient to say that the pelvic fascia has two attachments with regard to the vagina and cervix, namely, the bony pelvic wall and the sides of the vagina and uterine cervix. During parturition the vaginal and uterine attachment may be partially severed and permit considerable free movement of the uterus and vagina; therefore the total removal of the uterus must be so conducted that the pelvic fascia which is separated from the cervix and vagina, must be carefully measured and approximated exactly at the upper and outer angles of the inverted vaginal mucosa. If the anterior vaginal wall is short as it occasionally is, it may be lengthened by evaginating, so to speak, the cervix from the vagina by incising the tissues above the vesicovaginal fold of the mucous membrane of the vagina. Broad ligaments that are brought over the inverted vaginal vault are never as effective in their support as they are when shortened and left in their lateral position at the sides of the vagina. After the broad ligaments have been

Fig 8—Complete peritonealization. All vessels of ovarian ligament have been removed. The round ligaments and broad ligaments have been shortened and approximated at the angles of the vagina, providing a broad base for the bladder and excellent support for the vagina.

carefully approximated, the other uterine ligaments may be attached according to the usual standard techniques.

CONCLUSIONS

I wish to emphasize that, since operations on the uterus occasioned by myomas are among the most frequent gynecologic procedures, each patient must be carefully studied and the method of procedure determined by the position of the myoma, whether the tumors are single or multiple, and by the age of the patient. If hysterectomy is indicated, a careful inspection of the cervix is obvious in choosing between the total or subtotal technique. Finally, the support of the cervical stump or vaginal vault, as the case may be, may determine the success or failure of the operation so far as the patient is concerned.

ABSTRACT OF DISCUSSION

DR THOMAS S CULLEN, Baltimore. After spending my spare time for nine years in studying nearly 1,700 cases of uterine fibroid tumors encountered in the practice of Dr Howard A. Kelly, in my own and in those of our associates, Dr Kelly and I in 1909 published the results in a volume entitled "Myomata of the Uterus." In it the clinical side, the operative results, the follow up and the histology were fully considered. In our publication of 1909, supravaginal hysterectomy was advised in the cases in which the cervix was not diseased. We still favor the supravaginal removal in the majority of the cases. I was interested to learn that in the Mayo Clinic the same rule is followed, unless contraindications exist.

For years we have advocated the immediate opening of the uterus on removal. Occasionally an early carcinoma of the body will be detected, and then the cervical stump will immediately be removed. In any case in which the possibility of sarcoma exists the myomas are bisected immediately and if there is any suspicion of malignancy the cervix also is removed. Supravaginal hysterectomy has given us the best results. In clinics in which many Negro women are operated on we frequently find dense pelvic inflammatory masses complicating removal of the uterus. In such cases a total hysterectomy would add greatly to the danger. In many of these cases, before removal of the uterus, it would be almost impossible to locate the ureters. The vermicular contraction of the ureter on gentle teasing was especially emphasized by Dr. Kelly in the early days of the Johns Hopkins University School of Medicine, and for over thirty years this has been called the "Kelly sign." When a myoma is found spreading out in one broad ligament, Dr. Kelly pointed out that, if the operator starts on the opposite side and then cuts across the cervix, the broad ligament tumor can be rolled out with little or no danger of injuring the ureter. This was called the "right to left, or left-to-right operation." In those cases in which a single large myoma literally fills the pelvis and no vantage point can be obtained I have found it advisable to shell out this large tumor. Half a dozen spurting vessels have to be caught, after which there is ample room to complete the supravaginal hysterectomy. In other cases in which the myomatous uterus is densely adherent posteriorly, or in which an abscess in the myoma opens into a loop of bowel but in which the cervix is relatively normal, I have found it advisable to push down the bladder, cut across the cervix, clamp and cut the uterine vessels, clamp and cut the ovarian vessels, pack the pelvis with gauze and then loosen up the myomatous uterus. When the uterus is large, contains sloughing, submucous myomas that do not project into the cervical canal, the uterus is freed as for a supravaginal hysterectomy. Next a mattress suture is passed through the cervix and tied, and the uterus cut across below the suture. This procedure ensures that none of the contents of the uterus can escape when the cervix is cut across. In such a case we invariably leave one drain in the pelvis, bringing its outer end out through the abdominal incision.

DR. LOUIS E. PHANEUF, Boston. Dr. Counsellor's paper covers the surgical treatment of uterine myomas exceedingly well. The injection of solution of posterior pituitary into the tumor before clamping a vascular pedicle in order to return all possible blood to the circulation is a valuable procedure, which, in my opinion, is not resorted to often enough. The ureter should be identified during an operation for an intraligamentous myoma. In large myomas retrograde pyelo-ureterography will give considerable information on the relationship of the ureters to the tumor. In some instances it is of value to catheterize the ureters sometimes before operation to determine this relationship. In the surgical management of pedunculated myomas extruded into the vagina, Dr. Counsellor does not mention vaginal hysterotomy. This method has served me well in a number of instances, especially when the tumors had large pedicles with a high attachment within the uterine cavity. I agree that it is inadvisable to do an abdominal hysterectomy in the presence of a pedunculated myoma extruded into the vagina because of the danger of sepsis and also that following a vaginal myomectomy an abdominal hysterectomy should not be undertaken until the cervix is completely healed. Cervical myomas may present numerous surgical difficulties. My own practice is to enucleate them and identify the ureters and uterine vessels before proceeding with a hysterectomy. While I agree with Dr. Counsellor that myomectomy is one of the most satisfactory operations in gynecology, the fact remains that this intervention carries more danger from sepsis and hemorrhage than supravaginal and total hysterectomy. Treatment of myomas is surgical whenever possible. In my hands irradiation is reserved for women considered poor surgical risks and for those whose tumors are not complicated by adnexal disease and are not larger than a three months gestation. I also agree with Dr. Counsellor in what he has said regarding subtotal versus total hysterectomy.

DR. HENRY SCHMITZ, Chicago. The forms of treatment in uterine myomas are as diversified as the types of surgical treatment. The result is that the opinions of the efficacy of a given treatment vary, and confusion is prevalent. The selection of the indicated method of treatment will be facilitated by a study of the symptoms in relation to the age and the physical condition. The presenting symptoms are menorrhagia or hypermenorrhea, metrorrhagia and pain. The latter is either a pressure pain or an inflammatory pain. Menorrhagia is associated with the intramural myoma but is frequently an expression of endocrine dysfunction. Metrorrhagia occurs with loss of surface continuity of the endometrium often because of a complicating carcinoma or a degeneration of the myoma or a pedunculated submucous myoma. Pain is due either to limitation of space when the tumor becomes incarcerated in the bony pelvis on account of cervical isthmus intraligamentary or subperitoneal development or to the weight of a large myoma. Inflammatory pain is associated with degeneration of the myoma, axial rotation of the pedunculated myoma, and endogenous or exogenous infection. The age period is important, as radical procedures of treatment should not be used in the young and mature woman in whom sex functions especially fertility, should be conserved. The only treatment which accomplishes removal of growth and conservation of all functions is myomectomy. In all other age groups, that is the menopausal and the senile, radical measures of treatment are indicated. The menorrhagic myoma indicates conservative treatment, that is, palliation or myomectomy during the juvenile and mature age groups and radiologic treatment during the menopausal age period. The metrorrhagic myomas indicate myomectomy during the juvenile and mature age groups, and hysterectomy during the menopausal and senile age groups. The painful myomas always demand surgical intervention, as the kind of degeneration or complication in the myoma cannot be diagnosed positively by examination.

DR. VIRGIL S. COUNSELLER, Rochester, Minn. I want to express my appreciation to Drs. Cullen, Phaneuf and Schmitz for their discussion of this paper. It is from such men, who have spent years in the management of these conditions and who have written extensively that physicians gain information and correct advice. The question of hysterotomy, which Dr. Phaneuf has mentioned, I did not refer to in my paper. It is quite right that it should have been mentioned, because, as Dr. Phaneuf states, it is a very satisfactory approach to some pedunculated tumor, situated high, in which the cervix has not softened so that one could gain approach to the peduncle, and it is necessary to remove some of these tumors on account of inflammation and bleeding long before the cervix has softened sufficiently to expose the peduncle. Perhaps I am a little over-enthusiastic about myomectomy, because I feel that conservative procedures in the case of women under 35 should always be carried out, but judgment must be exercised, as Dr. Phaneuf and Dr. Cullen have stated about whether one does myomectomy or not. It is a much more difficult procedure than hysterectomy, because the technique has to be varied to conform to the situation encountered. A good many years ago Dr. W. J. Mayo reviewed his results in 700 cases in which myomectomy was performed and he brought out some interesting things which I have tried to utilize. One of them was the prevention of hemorrhage by advising and seeing to it that the assistant maintained traction on the uterus at all times. If there is extreme traction bleeding is not prevented but it is reduced so that one can cut directly down to the myoma keeping in mind that the vessels are in the cleavage plane and that myomas in them cleave relatively free from blood. If one is in the proper cleavage plane, one can enucleate them and their enucleability is distinguished from that of adenomyomas which cannot be enucleated. Dr. Mayo likewise pointed out that if one does not suture too tightly so that the tissue is not blanched infection and necrosis are not apt to occur. I believe that myomectomy is an operation which must be carried out by those who are experienced pelvic surgeons, except of course in the case of tumors that are easy to clip off.

HEMATOGENOUS PULMONARY
TUBERCULOSIS

WILLIAM A. ZAVOD, M.D.

VALHALLA, N. Y.

My purpose in this article is to draw the attention of the medical profession to a paradox that is occasionally encountered in comparing the roentgenologic and the clinical appearances in certain cases of pulmonary dissemination of the tubercle bacillus. A roentgenogram of the lungs invaded by such a dissemination will show miliary seeding throughout both lungs and the roentgenologist will justly report "miliary tuberculosis." The clinical picture, however, while that of miliary tuberculosis in some cases, will show very little to justify such a diagnosis in others. Though the phthisiologist is familiar with this benign type of hematogenous tuberculosis and the theories of its pathogenesis, the condition is frequently puzzling to the general practitioner, who is usually the first to see the patient. Indeed, having received a report from the roentgenologist that the patient is afflicted with miliary tuberculosis, he is apt to give a grave prognosis only to find some of these patients, months later, well and very much alive, while in another case with a similar roentgen diagnosis death may ensue within a few weeks to a few months. The difficulty lies in the fact that the fatal type of miliary tuberculosis and the comparatively benign dissemination "hematogenous tuberculosis" appear nearly alike roentgenographically, and one must turn to the clinical signs and symptoms and possibly to a period of observation as the basis for a differential diagnosis.

Pulmonary hematogenous tuberculosis is a pulmonary dissemination of the bacillus of tuberculosis by way of the lesser blood circle mainly in contradistinction to generalized miliary tuberculosis, which is a widespread dissemination of the bacillus of tuberculosis by way of both the greater and the lesser blood circles.

As has been repeatedly proved, tubercle bacilli circulate in the blood stream of many tuberculous patients not ill with miliary tuberculosis. Similarly tubercles may be found in the abdominal viscera, especially the spleen and kidneys at postmortem examinations of patients who died of tuberculous pneumonia or phthisis without any clinical or pathologic evidence of active generalized miliary tuberculosis. Solitary tubercles are also found in systems other than the pulmonary in many cases of hematogenous tuberculosis, but they are few in number and show no evidence of progression, as is seen in generalized miliary tuberculosis. What is responsible for the take and implantation of the tubercle bacillus at some time and not at another, or the involvement of a single system or organ (genito-urinary, bone, joint) or generalized involvement (miliary tuberculosis) and whether it is the number of organisms thrown into the blood stream, their virulence or the state of immunity in the patient's body as a whole or the immunity of a single organ or system are matters of lively debate among the several schools of phthisiologists and pathologists here and abroad. The subject is exceedingly interesting but does not enter into the scope of this paper.

The term "hematogenous tuberculosis" for this form of localized pulmonary tuberculosis is a misnomer, since miliary generalized tuberculosis, genito-urinary tuber-

culosis, tuberculosis of the bones and joints and the like are all blood borne infections and a more suitable, though not absolutely correct term, would be "lesser circle tuberculosis." However the term hematogenous tuberculosis had been in use by phthisiologists for the more benign blood stream dissemination limited clinically to the lungs, while the fatal widespread form is known as "generalized miliary tuberculosis."

HISTORY

Villemin showed in 1865 that active tuberculosis can develop in animals when they are injected with the blood of tuberculous patients not ill with miliary tuberculosis. Wunderlich, Koening and Cornet and others have reported cases of healed miliary tuberculosis. Sigg and Burckhardt have made similar reports with autopsy controls. Assmann reported in 1913 a case of healed miliary tuberculosis with roentgenographic evidence. Grau, Muralt, Klingenstein, Diel and others were the earliest observers in the last two decades to report cases of hematogenous tuberculous disseminations with serial roentgenograms showing retrogression. Von Graeff, Braeuning and Redeker in Germany and James Alexander Miller and Max Punnet in this country have in the last decade contributed much to our knowledge of the disease.

ETIOLOGY

Pulmonary hematogenous tuberculosis occurs most frequently during childhood and in young adults who were heavily exposed to tuberculosis during childhood. Repeated attacks are not infrequent. Continued close contact with open cases of tuberculosis favors repeated disseminations, especially in childhood. Undernourishment and general poor health are additional predisposing factors.

FIG. 1 (case 5).—Condition on admission. Widespread nodular dissemination miliary in character through both lungs. Enlarged tracheobronchial glands with perifocal reaction. Sputum positive no fever.

PATHOGENESIS

During the primary tuberculous infection the lymphatics that drain the tuberculous area carry tubercle bacilli to the regional lymph nodes, which are not perfect filters, some of the organisms enter the blood stream. When the nodes become tuberculous and caseate, the tubercle bacilli pass up the chain of lymph nodes until they reach the venous angle into which the lymphatic trunks empty. The infectious organisms invade the venous blood going to the right side of the heart and are then disseminated by way of the pulmonary arteries through the lung fields. Most of the tubercle bacilli lodge in the pulmonary parenchyma and but few organisms enter the pulmonary venous circulation, to be carried to some distant organ by the general circulation.

Reactivation of apparently healed tuberculous hilar nodes in young adults who have been heavily exposed to open tuberculosis during childhood may lead to hematogenous dissemination similar to the cases seen in childhood.

PATHOLOGY

The tubercle bacilli lodge in the pulmonary parenchyma and may call forth either an exudative reaction characterized by round cell infiltration or a productive reaction characterized by large mononuclear cells and giant cells (typical tubercles), or a mixture of the two types of reaction. Fibrosis of the interstitial structures is seen early. Dense round cell infiltration is frequently

Fig 2 (case 5).—Appearance four months later. Marked clearing of the nodular infiltrations with the disappearance of the perifocal reaction around the still enlarged tracheobronchial lymph nodes. Sputum negative.

seen along the vesicle wall, especially in the neighborhood of the blood capillaries. The interlobular septums become thickened and may show organized tubercles. The bronchioles show fibrosis along their outer walls. All lesions usually appear to be of the same age, when the lesions are of different ages, in the process of evolution, it suggests repeated dissemination. The uninvolved pulmonary parenchyma interposed between the minute fibrosing nodules shows obstructive emphysema going on simultaneously with the fibrosis in the involved areas. The tracheobronchial lymph nodes are either still enlarged and often caseous or they may be infiltrated with calcium salts.

EVOLUTION

Hematogenous dissemination can clear without leaving a trace (fig 2) that can be detected on physical examination or in some cases even roentgenographically. Pathologically, however, permanent parenchymal changes remain but their etiologic factor may be difficult to prove. From this extreme the evolutionary process may gradually lead to the other extreme of conglomeration of tubercles, caseation, softening, liquefaction, excavation, bronchogenic dissemination and eventually phthisis. The disease may become arrested in any of its evolutionary stages and never recur, or the patient may suffer repeated attacks of hematogenous dissemination, each succeeding spread involving more pulmonary parenchyma, increasing the emphysema and the interstitial fibrosis until a time is reached when, though the tuberculous process may be completely arrested, the patient becomes an invalid because of a state of partial anoxemia due to marked loss of lung tissue. He may die of heart failure due to exhaustion of the overtaxed heart muscle.

SYMPTOMS

The symptoms at the onset vary with the acuteness of the disease but they are seldom dramatic. The onset may be indefinite as to time, in some cases the condition may be discovered accidentally or on routine examination. There is usually a history of either recent pleurisy or repeated attacks of pleurisy in the past. There may be a rise in temperature of from 0.5 to 1.5 degrees, lasting a few days. Some dyspnea may be present though not always noted by the patient until his attention is called to it. In extensive disseminations there

may be some cyanosis. There is usually a moderate loss in weight and some dry cough. Expectoration is scant or entirely absent.

SIGNS

The patient is usually a child or a young adult moderately well nourished and well developed. Expansion of the chest is usually limited but equal bilaterally. The supraclavicular and infraclavicular fossae are well filled. The trachea is in the midline, palpation gives no additional information. The percussion note is normal or slightly hyperresonant. On auscultation one finds that the breath sounds are somewhat harsh and that there are fine subcrepitant rales extending from the apex to the base of each lung and more numerous in the upper halves. The blood picture is usually normal. The red cell sedimentation rate is usually above normal. The tuberculin test may be negative even to 1 mg of old tuberculin but will invariably become positive within a few weeks or within several months. The sputum, if there is any, is usually negative on direct examination of the concentrated specimen and on animal inoculation. The urine is negative for tubercle bacilli. The vital capacity is always lowered in some cases as much as 50 per cent.

CLINICAL COURSE

If the process is retrogressive the aforementioned signs and symptoms may subside within a few months and physical examination after retrogression is usually negative. The vital capacity usually increases, since the alveoli involved by nonspecific exudative reaction resume normal functioning after clearing. When the process is progressive expectoration usually appears but the sputum may never become positive for tubercle bacilli if the disease becomes arrested in the precavernous stage. When cavitation occurs the sputum becomes positive for tubercle bacilli. Bronchogenic dissemination manifested by fever, sweats, coarse and fine rales and pathologic breath sounds may appear in some cases, in others, spread of the disease does not occur in spite of persistence of the cavity for months. The cavity may eventually disappear without evidence of spread by way of the bronchi. Cavitation may occur concomitant with retrogression (figs 5, 6 and 7). Fulminating hematogenous tuberculosis is infrequent, it is usually progressive and fatal.

Hematogenous disseminations recur. Rales reappear with every new dissemination and disappear after clearing of the infiltration. When the individual foci conglomerate and undergo fibrous change, the rales, especially in the upper halves of the lungs, may persist throughout life even though the disease has healed and remained arrested. If the hematogenous invasions do not go to a phthisical evolution, i. e. if no progressive bronchogenic spreads occur, the pathologic physiology even in far advanced disease produces hardly a change in the contour of the chest or in the position of the intrathoracic organs so characteristic of chronic tubercu-

Fig 3 (case 6).—Condition on admission. Widespread very fine nodular dissemination miliary in type. Sputum negative, no fever, tuberculin reaction negative.

culosis The interpretation must be sought in the peculiar pathologic phenomena The disease is bilateral, equally distributed in the two lungs and affects all involved portions of the lungs simultaneously The pathologic changes, therefore, such as emphysema and fibrosis, usually occur equally and concurrently in all portions of the lungs The parenchymal distribution of the disease is such that it involves areas throughout the lungs only a few millimeters or less in diameter, and the intervening pulmonary tissue is not involved directly by the tuberculous process but continues to function Along with the fibrosis, emphysema develops around each focus so that the lung as an organ is not decreased in size, though markedly decreased functionally, and therefore there is no displacement of the heart, the mediastinum or the trachea and there are no secondary changes in the shape and the appearance of the thorax

When the hematogenous disseminations lead to progressive bronchogenic spread, the pathologic changes, physical signs and symptoms are those of phthisis, and all evidence of hematogenic origin may disappear

focal reaction around the fine nodules The hilar lymph nodes may either still be large or show heavy calcium deposition Periodic roentgenograms of retrogressive lesions show a gradual caudo-apical fading out of the infiltrations, and the nodules in the upper portions of the lungs persist the longest In some cases all roentgenographic evidence of disease may disappear within a few months to a year In other cases the fine hematogenic nodules may become fibrosed or even calcified and persist throughout life Dense invasions of the upper halves of the lungs may lead to heavy fibrosis, appearing as dense homogeneous shadows symmetrically distributed, the lower halves show increased transillumination due to emphysema

DIAGNOSIS

Diagnosis is based on (1) a careful history, especially one of close contact with open tuberculosis during childhood, repeated attacks of pleurisy, (2) age of the patient (childhood or early adult life), (3) protracted mild onset, (4) symmetrical distribution of physical

* Case histories reported in this article

† + positive — negative

When the hematogenous invasion is very dense in the upper halves of the lungs, the subsequent changes frequently lead to heavy fibrosis in those regions and to emphysema in the lower, less involved, halves On physical examination in such cases there are dullness, bronchovesicular breath sounds and sometimes squeaky grating rales in the upper halves, while signs of emphysema are found in the lower halves The chest in these cases shows definite evidence of underlying pathologic changes the upper halves may be shrunken the interspaces are narrowed and the superficial veins of the thorax are dilated and stand out, but the changes are bilateral and symmetrical Expectoration, when present, is often negative for tubercle bacilli and is due largely to bronchiectatic changes in the upper lobes secondary to the tuberculous process Hemoptysis in the presence of a negative sputum is not infrequent in these cases

ROENTGENOGRAPHY

Early hematogenous disseminations show an evenly distributed seeding of nodules varying in size from one to several millimeters, with the greatest density in the upper halves In the earliest stages the roentgenogram may show a mottled appearance owing to peri-

signs, (5) presence of cough and absent or scanty sputum in the presence of widespread rales, (6) roentgenographic appearance of the lungs, showing a milary nodular dissemination without clinical evidence of generalized milary tuberculosis

A diagnosis of hematogenous tuberculosis must always be confirmed by a roentgenogram, since the physical signs alone are not sufficient criteria for diagnosis or treatment

PROGNOSIS

The prognosis is usually favorable, except in the fulminating type, which is fatal in most cases

DIFFERENTIAL DIAGNOSIS

The disease that is most frequently confused with hematogenous tuberculosis is generalized milary tuberculosis Careful clinical and laboratory study will usually obviate any difficulty that other diseases simulating hematogenous tuberculosis may offer Occasionally a case is encountered that permits no definite antemortem diagnosis with present methods of investigation

1 *Miliary Generalized Tuberculosis*—The symptoms and signs of acute milary tuberculosis are usually

clear cut and present no difficulty. The more chronic forms of miliary tuberculosis are slowly progressive with increasing debility and loss in weight, slight fever persists, sooner or later there will be evidence of involvement of other systems than the pulmonary. In some cases a period of observation may be necessary to decide whether the process is generalized miliary tuberculosis or a localized hematogenous pulmonary dissemination.

Fig. 4 (case 6)—Appearance twenty-two months later. Complete clearing of all nodular infiltration. Residual light diffuse fibrosis. Tuberculin reaction positive.

2 Pulmonary Congestion—(a) When due to cardiac decompensation, the râles are loud, wet and often gurgling, and they decrease in intensity and number from below upward (the reverse of hematogenous tuberculosis). Signs of heart disease may be present. The appearance of the

roentgenogram showing cardiac enlargement and heavy clouding of the lower lung fields is indicative of pulmonary congestion. (b) Congestive heart disease or heart disease that causes long standing passive congestion may offer difficulty, since heart failure cells gather into small clumps in the alveoli, which throw a nodular shadow on the roentgenogram not unlike the nodules seen in hematogenous tuberculosis. The accompanying fibrosis adds to the confusion of the picture. The enlargement of the heart, cyanosis in the absence of marked dyspnea, the presence of murmurs and the absence of all evidence of inflammatory pleuritic involvement would be against a diagnosis of tuberculosis.

3 Miliary Carcinomatosis—This usually occurs in older persons, the dyspnea is progressive, evidence of carcinoma may be found elsewhere and the appearance of the roentgenogram establishes the diagnosis.

4 Fungous Infections—Abundance of fungi in the sputum that are pathogenic on animal inoculation, and more profuse expectoration that is negative for the bacillus of tuberculosis establish the diagnosis. The roentgenographic appearance is that of ill defined patchy infiltrations much larger in size than is found in hematogenous tuberculosis.

5 Hodgkin's Disease of Miliary Distribution—The nodules in this disease are more discrete and there is no tendency to confluence and no evidence of cavitation. There is progressive enlargement of the lymph glands in the mediastinum.

6 Silicosis—There is a history of exposure to dusts of free silica or silicates. The dyspnea is slowly progressive. Roentgenographically the nodular infiltrations are more limited to the midportions of the lungs and tend to become confluent and densely fibrotic. The upper portions of the lungs are much less involved.

TREATMENT

When active hematogenous tuberculosis is suspected the patient should be placed on complete bed rest, preferably in a tuberculosis hospital or sanatorium. When the diagnosis of tuberculosis is definitely estab-

lished the patient should be treated as having active pulmonary tuberculosis until monthly roentgenograms demonstrate whether the process shows a tendency to retrogression or progression or is stationary. When the condition is stationary and inactive for two or three months, as determined by roentgenogram, physical examination and the clinical course, the disease is probably arrested and the patient may be discharged. When there is evidence of retrogression, the patient should be kept at rest in bed until either the process clears and the roentgenogram shows disappearance of the nodular infiltrations or it becomes stationary, i. e., when periodic roentgenograms fail to show change. The patient is then gradually permitted to return to a normal life. When there is progression of disease with cavity formation, the patient should be on absolute bed rest for at least three months. If at this time the periodic roentgenograms demonstrate that the cavity did not disappear or at least showed no tendency to decrease in size, or if there is evidence of progression at any time, collapse therapy should be employed and the same treatment employed as for any other case of pulmonary tuberculous disease similar in extent and of other than hematogenous origin.

After the disease has become arrested the patient should have a periodic physical examination including analysis of the sputum and roentgen examination, since hematogenous pulmonary tuberculosis has a tendency to recur.

The accompanying table presents a group of cases of hematogenous pulmonary tuberculosis that have come under our observation at the Grasslands Hospital in the last two years. All these cases were referred to the institution with a diagnosis of either "acute miliary tuberculosis" or "miliary tuberculosis" made by the family physician or the public health clinics. Our diagnosis was "hematogenous pulmonary tuberculosis," and though a similar diagnosis was made by the staff at the hospital in a much greater number of cases, only those cases showing roentgenographic evidence of a miliary type of dissemination similar to generalized miliary tuberculosis were included in this table.

Though the number of patients in the table is small, a few interesting points can be noted: 1 Seven of the eight patients had pleurisy at the time of onset of the disease. 2 The vital capacity is an important indicator of the pathologic changes taking place in the lungs. Old and inactive lesions show little change in the vital capacity while under observation, lesions that undergo clearing and but partial fibrosis show a decided increase in the vital capacity. 3 Râles persist in old inactive lesions that have undergone fibrosis.

The following are more detailed reports of cases 5, 6 and 8 listed in the table. They represent the evolution

Fig. 5 (case 8)—Appearance on admission. Widespread very fine dissemination in character with tracheobronchial glandular enlargement. Sputum negative. Tuberculin reaction negative. No fever.

that some of the hematogenous pulmonary disseminations undergo while under observation

CASE 5—W W, a white man, aged 31, admitted May 25, 1936, complained of loss in weight and fatigability. The condition was diagnosed before admission as "miliary tuberculosis." While a child he was in contact with his brother, who died of pulmonary tuberculosis.

Fig 6 (case 8)—Appearance ten months later. Marked clearing of nodules. Cavity appeared on right in second interspace anteriorly, thin wall, no pericavernous reaction. Sputum positive, tuberculin reaction positive, no fever.

hyperresonant, there were normal breath sounds, with very fine rales extending from the apex to the base. The diagnosis was hematogenous tuberculosis.

Laboratory examination revealed red blood cells, 5,400,000, hemoglobin 85 per cent, white blood cells, 12,400, polymorphonuclear leukocytes, 55 per cent, lymphocytes, 42 per cent, mononuclears, 3 per cent. The urine was normal, the vital capacity was 2,000 cc (48 per cent), the tuberculin reaction positive to 1 mg of old tuberculin, examination of the sputum was negative. The heart was normal.

The temperature remained normal throughout the patient's stay in the hospital, with the pulse from 80 to 90 and the respiration rate from 18 to 20. The patient was on strict bed rest for three months, ambulant for one month and discharged with apparently arrested tuberculosis. During the first two months of his hospital stay he lost in weight from 142 to 132 pounds (64 to 60 Kg) after which he began to gain rapidly and weighed on discharge 168 pounds (76 Kg). Monthly roentgenograms showed gradual clearing of the nodular deposits and marked decrease in size of the tracheobronchial glands. The vital capacity rose to 3,100 cc (64 per cent). The rales disappeared completely.

This patient apparently had active hematogenous pulmonary tuberculosis with marked involvement of the tracheobronchial nodes. There was no evidence of involvement of any other system or organ that could be determined by clinical or other investigation. The process retrogressed by gradual resorption of the miliary nodules in the pulmonary parenchyma and partial fibrosis.

CASE 6—P D, a Negroess, aged 25, admitted May 23, 1934, complained of cough, loss in weight and slight expectoration. There was no known history of contact with tuberculosis. The onset was noted in January 1934 with dry cough and pleurisy one month later. She began to expectorate 1 ounce (30 cc) of thick sputum. She lost 11 pounds (5 Kg). She was examined at the board of health clinic, diagnosed as having miliary tuberculosis and admitted. Physical examination was negative throughout except for fine rales extending from the apex to the base of both lungs.

Laboratory examination revealed red blood cells, 5,600,000 hemoglobin, 82 per cent, white blood cells, 7,200, polymorphonuclear leukocytes, 50 per cent, lymphocytes, 46 per cent, mononuclears, 4 per cent. The vital capacity was 1,600 cc (53 per cent), examination of the sputum was negative for tubercle bacilli by the concentration method and guinea-pig inoculation and negative for fungi, the urine was normal. The tuberculin reaction was negative with serial dilutions up to 1 mg of old tuberculin. There was no fever. The weight was 117 pounds (53 Kg). The diagnosis was hematogenous tuberculosis and pleurisy.

The temperature remained normal throughout the patient's stay in the hospital and expectoration gradually disappeared. She was discharged in December and has been followed in the clinic since. The weight on discharge was 133 pounds (60 Kg). Physical examination on discharge was negative. The vital capacity rose to 2,300 cc (75 per cent). The tuberculin reaction was strongly positive to 1 mg of old tuberculin, examination of the sputum was never positive. Periodic roentgenograms showed gradual clearing of the fine nodular deposits (figs 3 and 4).

A diagnosis of hematogenous pulmonary tuberculosis was made in this case by exclusion since clinical and laboratory studies failed to show evidence of disease that might simulate hematogenous tuberculosis. The roentgenograms on admission showed enlarged tracheobronchial nodes in addition to the dissemination, and both cleared on bed rest. The tuberculin test became positive, having been repeatedly negative on admission.

CASE 8—C J, a Negro youth, aged 17, admitted Sept 29, 1934, complained of loss of weight, pain in the chest, shortness of breath and a slight cough. The onset was noted in February 1934 with coughing and fever. He began to lose weight and noticed dyspnea. A few months later slight expectoration appeared. He was referred to the hospital with a diagnosis of "miliary tuberculosis." Physical examination on admission showed good expansion, normal resonance, bronchovesicular breath sounds and many fine rales over both lungs. The heart was normal. There was pain in the chest on deep inspiration and slight generalized adenopathy of all superficial lymph nodes.

Laboratory examination revealed red blood cells, 4,860,000 hemoglobin, 88 per cent, white blood cells, 6,000, polymorphonuclear leukocytes, 52 per cent, lymphocytes, 21 per cent, mononuclears, 27 per cent. The vital capacity was 1,100 cc (30 per cent). Examination of the sputum was negative on concentration and guinea pig inoculation. The urine was normal, the tuberculin reaction was repeatedly negative to 1 mg of old tuberculin.

Roentgenographic examination showed dense fine nodular dissemination through both lungs and marked enlargement of the tracheobronchial nodes (fig 5).

The patient failed to improve though he was on complete bed rest. His weight dropped from 119 pounds (54 Kg) on admission to 106 pounds (48 Kg) six months later. The epitrochlear lymph gland was excised and histologic study showed tuberculous infiltration with typical tubercles. Periodic roentgenograms showed gradual clearing of the nodules in the lungs. In July 1935 a cavity 2 cm in diameter appeared in the second interspace anteriorly (fig 6). Expectoration at this time was 2 drachms (7.8 cc) and positive for tubercle bacilli on direct

Fig 7 (case 8)—Appearance two months after condition shown in figure 6. The cavity is closed, sputum negative, no fever (fig 5).

smear Following the appearance of the cavity he began to improve and gain weight. Subsequent roentgenograms showed that the cavity closed in November and the sputum became negative. The nodular infiltrations cleared completely by roentgen examination. The patient was discharged in May 1936, at which time physical examination was negative. He gained in weight from 106 to 156 pounds (48 to 71 Kg). The vital capacity rose to 3,000 cc (70 per cent). The tuberculin reaction became positive to 0.1 mg. of old tuberculin.

This patient was at no time acutely ill except for an occasional rise in temperature to 100 F., lasting a day or two. The cavity appeared in spite of progressive clearing of the punctate infiltrations. It had a thin wall and no pericavernous reaction (punched out cavity of Redeker). It closed on bed rest (figs. 5, 6 and 7).

SUMMARY AND CONCLUSIONS

Hematogenous pulmonary tuberculosis is a definite clinical entity apart from miliary generalized tuberculosis. The prognosis in hematogenous pulmonary tuberculosis is favorable in most cases in contradistinction to generalized miliary tuberculosis, which is usually fatal.

STUDIES ON THE PATHOLOGY OF THE RENAL PAPILLA

RELATIONSHIP TO RENAL CALCULUS

ALEXANDER RANDALL, MD

JOHN E. EIMAN, MD

AND

PAUL R. LEBERMAN, MD

PHILADELPHIA

In three previous publications¹ certain deductions were drawn relative to the origin of primary renal calculi. These deductions seem to have been thoroughly supported and proved by the research work performed and therein reported. As subsequent studies have further substantiated these facts, it is pertinent to restate them at this time.

1 It was shown that all clinical data and all reasoning from the point of view of pathology require that a primary renal calculus must be stationary and attached while beginning and acquiring growth.

2 Small renal calculi, when examined under a magnifying lens, almost always show such a stoma, or facet, of mural attachment.

3 X-ray studies in proper cases repeatedly show that such primary renal calculi have their origin in the minor calices.

4 It was postulated and subsequently proved that an initiating lesion would be found.

5 It was postulated and subsequently proved that the initiating lesion would be found on the renal papilla.

6 In a series of postmortem investigations there was observed a new pathologic lesion of the renal papilla, consisting of a deposit of calcium in the basement membrane of the collecting tubules and in the intertubular connective tissue. Such deposits, or calcium plaques,

while intrapapillary were innocent of further trouble but when they occurred near the surface of the papillary wall they were prone to lose their surface covering of epithelium and, when so denuded, could and did act as the nidus on which the salts in the caliceal urine were deposited, and a stone was formed.

7 Such calcium plaque formation was observed in a relatively high percentage of the kidneys studied at regular autopsy, i. e., in 17 per cent of 429 autopsies in our series ending Feb. 15, 1937.

8 In this series twenty-eight examples of primary renal calculi were observed; the majority visibly supported by an underlying calcium plaque.

9 Calcium plaque material has been chemically analyzed and proved to consist of calcium carbonate, calcium phosphate and perhaps calcium nucleinate.

10 By chemical analysis pure calcium phosphate calculi and pure calcium oxalate calculi were proved thus to grow in man. In three further cases the tiny primary calculus was teased from its bed and shown (a) by photomicroscopy to be intimately attached to its papillary calcium plaque and (b) to be of different chemical composition than the plaque itself.

Such studies opened the way to an effort to reproduce these papillary lesions experimentally in lower animals, and the purpose of this paper is to present the results of our studies along these lines and to bring the post-mortem observations up to date (May 15, 1937), terminating an eighteen month period of investigation and a total of 609 autopsies.

As the lesions may be found singly and involving only one papilla in a pair of kidneys, or may appear on several papillae in one kidney, the opposite kidney being normal, or may be present in both kidneys, and as no predilection as to which papilla or kidney is first involved has been observed, it has been the custom to report as positive any pair of kidneys in which the lesion is present, without further detail as to place, multiplicity or bilaterality. To date (May 15, 1937) the kidneys from 609 autopsies have been examined. The calcium plaque lesion was observed in 140 of them, so that the incidence of occurrence was 22.9 per cent.

In the same series of 609 autopsies, forty-nine papillae, with stone growing thereon and adherent thereto, were observed, as follows: In fifteen autopsies a single stone was observed, in ten, two calculi were present in one kidney (in one autopsy each kidney had two), and in one kidney all six papillae were stone bearing. This makes a total of forty-one examples of primary renal calculus, each of which was firmly adherent to its individual papilla, and in practically every one a supporting calcium plaque could be seen underlying the stone. To this total may be added eight examples so small as to be called "cinders," definite tiny black specks which, under a magnifying lens, could be seen as foreign material in the center of a calcium plaque and which, on microscopic study, proved to be crystalline. In two further specimens multiple small calculi were observed in a minor calyx, none over 2 mm. in diameter, but non-adherent to the papilla, and in one of the two specimens this condition was bilateral. Omitting the last two cases but including the tiny "cinder" specimens we report forty-nine examples of stone formation each of which had its origin on a renal papilla. On the basis of the occurrence alone of stone in this group of specimens the eight cases of "cinders" being omitted we observed forty-one examples of true primary renal calculi in twenty-five autopsies which makes the incidence of the simple occurrence of stone, or stones 41 per cent.

Read before the Section on Urology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.

The autopsy material was received from the Departments of Pathology of the University of Pennsylvania School of Medicine, the Abington Memorial Hospital and the Philadelphia General Hospital. The experimental work on animals was performed in the Department of Surgical Research and in the Wistar Institute of the University of Pennsylvania and in the laboratories of the Abington Memorial Hospital.

Urol.* 38: 253 (June) 1937; Randall Alexander, "Observation on the Origin and Growth of Renal Calculi," *Ann. Surg.* 105: 1009 (June) 1937.

Our efforts to reproduce the papillary lesion have been approached through three separate problems, each of which was suggested by either clinical observation or previous experimental work. In each problem we have met with indifferent success, but it is to be remarked that as we were interested especially in reproducing what we consider a precalculus, or initiating, lesion, we have sacrificed a great many of our animals early in order to try to observe this lesion in its incipience.

THE RELATIONSHIP TO VITAMIN A DEFICIENCY

Rats of the Wistar Institute breed were used, and it is perhaps of particular significance that in the past they have shown themselves particularly resistant to the effects commonly caused by vitamin A deficiency diets. This is attributed to the high vitamin diet which they have been fed and to the storage of vitamin in their systems. They should be ideal for this experiment, as their vitamin loss is gradual and the experiment follows a more typical clinical and chronic course. This study has been devoid of positive results, though it is still being pursued, and of the eighty-two rats undergoing experimentation only forty-five have been killed to date. We are killing these animals at intervals and are searching for evidences of calcium deposition and perhaps other evidences significant of initiating lesions of the papilla. The basic diet has been casein 15 parts, salts (Osborn and Mendel²) 4 parts, irradiated yeast 10 parts, dextrin 53 parts and lard 18 parts. The following brief group protocols may be given.

Group 1 Six rats, 25 days old, were put on the diet Nov 21, 1936. One was killed on Jan 4, 1937, two on February 15, one on April 1 and two on April 16. Macroscopic and microscopic examination of the kidneys of each gave negative results. All were losing weight when killed.

Fig. 1—Cloudy swelling in the convoluted tubules of a rabbit's kidney after the administration of eleven daily injections of stable streptococcus hemolysin leukocidin.

Group 2 Six rats 92 days old, were put on the same diet on the same date. One was killed on January 19, one died on April 9 and one died on May 18. The examination of each gave negative results. The three remaining alive are gradually losing weight.

Group 3 Six rats 91 days old, were put on the same diet on November 21. One was killed on March 12. examination

gave negative results. The remainder are alive but losing weight and in poor condition.

Group 4 Six rats, 26 and 28 days old, were put on the diet on November 27. One died on May 6 and another on May 13. The kidneys did not show the expected lesions. Four of the animals are alive in very poor condition.

Fig. 2—The collecting tubules of a rabbit's kidney showing epithelial damage and tubular exudate after eleven daily injections of stable streptococcus hemolysin leukocidin.

Twelve of twenty-four rats have been examined post mortem (four had died). The expected lesions were not observed, though the animals still alive show characteristic signs of vitamin deficiency—marked xerophthalmia, loss of weight, weakness and generalized cachexia.

Group 5 Six rats 93 days old, on November 21 were put on vitamins A and D deficiency diets by the substitution of non-irradiated yeast 7 parts for the irradiated yeast 10 parts. One was killed on January 27 and another on February 5. Neither had lesions of the renal pelvis. The remaining four are in poor condition.

Group 6 Six rats, from 89 to 93 days old, were put on a similar diet November 21. One was killed on January 4. examination gave negative results. The remaining five are alive but losing ground.

Group 7 Six rats, 25 days old, were started on the same diet November 27. One was killed on January 19, another on February 15, and four on April 16, the kidneys were normal.

Group 8 Six rats 25 days old, were started on the same diet November 27. Two were killed on February 2, one on March 5 and three on April 16. the kidneys were normal.

Of twenty-four rats nine are still alive and fifteen were killed. All were on vitamins A and D deficiency diets. Some were given a few drops of cod liver oil (orally) on April 9 because of their poor condition and to prolong the experiment. No lesions of renal papillae were observed.

Group 9 Six rats, 27 days old were started on the vitamin A deficiency diet January 5. One died on April 6. examination gave negative results. The remainder are losing ground.

Group 10 Six rats 27 days old were started on the same diet January 5. One died May 12 and the kidneys were normal. The remaining five are in poor condition and have typical symptoms of vitamin A deficiency.

Group 11 Five rats, 27 days old, were started on the same vitamin A deficiency diet January 5. One died May 2 and the remaining four were killed. In one a bladder calculus was observed and the kidneys failed to show any calcium deposition.

² Osborn, T. B. and Mendel, I. B. Nutritive Value of the Wheat Kernel and Its Milling Products. J. Biol. Chem. 37: 557 (April) 1919.

These seventeen rats were similar to the first four groups but were kept and fed in separate cages. Three died, and four were killed. Most of them received a few drops of cod liver oil on April 7 because of their poor condition. Though in one a tiny bladder calculus was observed, macroscopic and microscopic examination of the kidneys did not show calcium deposition or pathologic change in the papillae.

Fig. 3—High grade epithelial damage in the terminal collecting tubules in the papilla of an experimental rabbit after eleven daily intravenous injections of stable streptococcus hemolysin leukocidin.

Group 12. Five rats, 28 days old, were put on Higgins' vitamin A deficiency diet on January 5. One was killed on February 15, one on March 5, one on April 3 and two on April 20. They were given yeast on February 13, 14 and 23 and on March 15 to keep them alive. The kidneys of all were normal.

Group 13. Twelve rats, 26 and 30 days old, were started on Higgins' diet January 22. Six have been killed and their kidneys observed to be normal and six are still alive and in fair condition.

These two groups comprised seventeen rats, eleven have been killed and their kidneys proved to be normal, and the others are to be tested further.

Four other groups have been under observation, and we mention them only as studies. In each animal the results were negative. Six old rats and six young rats were on a high salt diet (Hou¹), seventeen rats in three groups were on Higgins' diet and a final group, of ten rats, received parathyroid extract.

It is hardly necessary to do more than mention that by this work we have been striving to substantiate, in studies with animals, the pathologic changes that we have observed in man and that we know are closely related to the occurrence of primary renal calculus. That all the animals have not yet been killed and studied is to be noted for we have wanted to make a chronic and not an acute experimental condition and hope, by killing the animals periodically to observe early evidences that can be related to the origin of stone under the dietary conditions imposed.

THE RÔLE OF INFECTION

As, microscopically, the calcium plaque lesion was consistently devoid of any evidence of focal infection in the papilla, either in the appearance of organisms in the tissue or in tissue reactions characteristic of the presence of infection, it became evident that the introduction of bacteria per se was not essential to the problem. The effect of bacterial toxin is quite another matter and as the lesion gave every evidence of being a calcium deposition in response to some form of damage to the collecting tubules there was the possibility that the concentration of some such toxic material at this point could be the primary cause. In the laboratories of the Abington Memorial Hospital a staphylococcus toxin was elaborated, and we injected it into rabbits in a small series of experiments. This toxin proved to be too potent to work with accurately, and the animals died promptly after the injection of 0.2 cc, so a toxoid was prepared by the addition of 0.2 per cent of formaldehyde and incubated at 39 C from twenty-four to forty-eight hours. The experiments consisted of the intravenous injection of 5 cc of this toxoid, to be followed by simultaneous collection of blood and urine at frequent intervals over the following three or four hours for the titration of toxoid content. It was to be assumed that the concentration of the toxoid in the glomerular filtrate would be the equal of that in the plasma and that somewhere along the renal tubules concentration of the toxic material would occur, and we wished to find out if this could be observed.

In an experiment with a rabbit weighing 2,700 Gm in which 5 cc of staphylococcus toxoid of L. B. 001 was injected intravenously, subsequent titrations proved that at the highest reading this toxoid was present in the urine in a concentration five times greater than in

Fig. 4—Typical calcium plaque formation on the side of a papilla, dog 97 after the administration of parathyroid extract for six months. This is the first time that such a lesion has been observed in a lower animal.

the blood stream at its maximum concentration at five and ten minutes after injection. This rabbit secreted 0.13 cc of urine per minute.

In a second similar experiment a rabbit weighing 1,940 Gm was given an intravenous injection of 5 cc of the same toxoid of L. B. 002. This toxoid was recovered from the urine in a concentration sixty times

¹ Higgins, C. C. Experimental Production of Urinary Calculi. *Urol.* 29: 157 (Feb.) 1916.
² Hou, H. C. Influence of Diet on the Formation of Urinary Calculi. *Chinese M. J.* 30: 22 (June) 1916.

greater than that in the blood stream at its point of maximum concentration. The rabbit secreted 0.02 cc of urine per minute.

These examples, together with others, from our series of ten similar experiments, seem definitely to prove that the kidney can and does concentrate this toxic material from two and a half to sixty times the blood stream content. The tabulation and complete protocols of this experimental work have been reported by Dr Ezra Casman of the Abington Memorial Hospital before the Eastern Chapter of American Bacteriologists and are to be published in the *Journal of Bacteriology*.

Through the courtesy of Dr Stuart Mudd, professor of bacteriology, University of Pennsylvania, we were supplied with some of his stable streptococcus hemolysin leukocidin, we desired to use it because it is a haptin and does not give rise to the formation of antibodies when injected into animals. It was injected into a small series of rabbits, and the following protocols are characteristic.

Rabbit 8, weighing 1308 Gm, was given 1 cc of a 1:500 dilution on each of three consecutive days. Death followed the third injection. Grossly the kidneys showed no noteworthy lesions. Microscopically there was cloudy swelling of the epithelium of the convoluted tubules and albuminous exudate into Bowman's capsule. The collecting tubules showed marked degenerative changes. The lining epithelial cells were necrotic and in many places desquamated. In other places the basement connective tissue was damaged. At the very tip of the papilla was an area of necrosis.

Rabbit 6, weighing 1370 Gm, was given eleven daily injections of 1 cc of the same preparation in a 1:2500 dilution. The only lesions observed were microscopic and showed necrosis of a few cells in a number of the collecting tubules with no lesions in the glomeruli or in the convoluted tubules.

All the control rabbits were entirely normal.

Such kidneys present conclusive evidence that damage has been suffered by the epithelium of the renal tubules and though cloudy swelling is present in the convoluted tubules when high concentrations have been given, the greatest damage of all is in the terminal collecting tubules in parts of which even epithelial exfoliation can be observed (figs 1, 2 and 3).

These experiments seem to prove that the kidney does concentrate bacterial toxins while excreting them and that the elimination of a streptococcus toxin through the kidney can cause definite localized damage which is most marked in the walls of the collecting tubules. Naturally the concentration of any toxin in the urine varies inversely with the amount of urine excreted, and this fact carries attractive therapeutic implications. From it we deduce that either (1) the complete reparative process that follows an acute insult of such nature or (2) the kidney's reaction to lower grade but oft repeated, toxic insults could be directly associated with tubular and intertubular calcium deposition such as we have observed in man and described as calcium plaque formation. In either case it could be recognized as a natural sequel to insult and is comparable to calcium deposition as seen elsewhere in the body under similar circumstances. This experiment is to be pursued further.

THE RELATIONSHIP TO PARATHYROID HYPERTENSION

Fifteen healthy adult dogs were given parathyroid extract.⁵ Changes in the blood calcium were estimated at weekly intervals, and, when possible, estimations of

the urine calcium were likewise made. Practically every dog had one kidney removed after from two to five months' administration and was not killed for two or more months longer. Some of these dogs were given enormous doses of the parathyroid extract daily (as high as 500 units), and viosterol was added to the diet of some, as suggested by Johnson.⁶ Elevation of the blood calcium was difficult to obtain and still more difficult to sustain, though figures of from 12 to 14 mg per hundred cubic centimeters and in a few instances of from 17 to 19 mg were recorded. The kidneys removed surgically in the middle of the experiments were all completely normal, both macroscopically and microscopically. Of the remaining kidneys, on which the dogs lived while the daily administration of parathyroid extract was continued, one was completely normal, though a vesical calculus was present, and seven showed microscopically some small scattered depositions of calcium, generally occurring as intratubular deposits and rather generally scattered throughout papilla, medulla and cortex. We have one brilliant exception to report, for in the right kidney (the remaining one) of dog 97 was observed, on microscopic study only, a true and characteristic calcium plaque, similar and identical in every respect to that which we have observed in man in our postmortem studies. There was no evidence of stone growing thereon, as the plaque was still a sub-surface deposit on the side wall of the papilla. The following short protocols are representative of the entire group.

Dog 97 weighed 13 Kg. The administration of parathyroid extract was started November 17, the blood calcium content was 11.71 mg per hundred cubic centimeters. On January 6, 1440 units had been given, the blood calcium was 11.69 mg. On January 28 a left nephrectomy was performed, the kidney was normal. On March 8, 1,630 units had been given and the blood calcium was 10.50 mg. From March 12 to 22 was a rest period, and on March 25 10 drops of viosterol was added to the daily diet. On April 16, when 4,890 units had been given, the daily dose was increased to 500 units, and the administration of viosterol was continued. On April 28 the blood calcium was 15.9 mg, on April 29 17.3 mg and on April 30 18.4 mg. On May 4 the dog was killed. He had received 6,240 units of parathyroid extract and 1,475 drops of viosterol and his blood calcium was then 11.2 mg. The kidney, macroscopically, showed a tiny yellow speck on the papilla and, microscopically, a typical calcium plaque, similar in every respect to the ones we have observed in man (fig 4).

Dog 103 weighed 11 Kg. Administration of parathyroid extract was started on November 17, the blood calcium content was 11.53 mg per hundred cubic centimeters. On November 23 the blood calcium was 19.11 mg, and 800 units had been given. From November 24 to December 3 was a rest period. On December 21 the blood calcium was 12.23 mg. On March 11 a left nephrectomy was performed. At this date the dog had had 4,580 units of parathyroid extract and the blood calcium was 11.5 mg. The kidney was normal. After a rest period from March 11 to 23, he was given daily doses of parathyroid extract and viosterol until May 4, when he was killed. The highest blood calcium reading during this period was 14.1 mg on April 30 and he received, in all 8,460 units of parathyroid extract and 1,434 drops of viosterol. The right kidney was normal macroscopically, but microscopically small deposits of calcium could be seen scattered throughout papilla and cortex. They were mostly intratubular but were definitely associated with some epithelial damage.

Dog 131 weighed 16.9 Kg. Administration of parathyroid extract was begun November 30 when the blood calcium content was 11.22 mg per hundred cubic centimeters. On January 6 the blood calcium was 12.57 mg and he had received 615 units

On March 10 viosterol 10 drops per day was added to the diet and he had a rest period from March 3 to 22 from parathyroid extract. On April 8 a left nephrectomy was performed at which time he had received 5,055 units of parathyroid extract and 285 drops of viosterol the blood calcium was 9.45 mg. The left kidney was normal. The dose of parathyroid extract was increased to 200 units daily on April 12 and to 400 daily on April 26. The blood calcium on April 30 reached its highest point, 13.8 mg. The dog was killed on May 4, having received 7,055 units of parathyroid extract and 1,395 drops of viosterol. The bladder contained a thimbleful of fine round yellow calculi the largest measuring 3 by 4 mm. On analysis they proved to be composed of calcium phosphate. The right kidney was macroscopically normal but on microscopic study scattered deposits of calcium were observed throughout the papilla and cortex, as in dog 103.

A similar collection of bladder calculi was observed in dog 125.

This experiment with parathyroid extract which for long seemed the least promising, has been the only one to date in which we have observed a calcium plaque similar to those in man. It remains for us to associate this observation further with actual growth of stone. Even if the latter is accomplished, it cannot then be said that it comprises the only etiologic factor capable of causing calcium deposits in the renal papilla. That the experiment provides a lead quite in keeping with clinical experience and the prevalence of renal calculus in cases of hyperparathyroidism is not to be lost sight of. That it offers the only observation that has been made of the occurrence of papillary calcium plaque formation in lower animals is, of itself, most interesting. Of course, it is quite presumptive to accredit to the administration of the parathyroid extract the entire responsibility for this lesion, as primary renal calculus in the dog is not unusual and this might be but a fortuitous observation. Also, we wish to state that this papilla showed several areas of localized round cell infiltration without any necrosis, that they were remote from the calcium plaque and that there was no calcium deposition near by.

COMMENT

We wish again to point out the quite obvious and self-evident fact that primary renal calculus is but the crystallization of the common urinary salts on a pre-existing papillary lesion, that during the time of such asymptomatic growth a stone is adherent to the papilla, and that we have observed such growth in 41 per cent of the autopsies performed. We have made observations to date on 609 autopsies, and in this material we have again noted the prevalence of a papillary lesion consisting of a deposition of calcium salts and have shown that primary renal calculi can and do grow thereon. Such calcium deposition, or plaque when intrapapillary is innocent enough, but it can lose its epithelial covering and when so denuded, is bathed in calceal urine and acts as the nidus on which crystallization occurs. This fact we have proved in a number of cases previously reported, and we have shown a difference between the chemical composition of such a papillary calcium plaque and that of the true stone.

We have tried to reproduce this papillary lesion experimentally by vitamin-deficient diets, by injection of toxin and by administration of parathyroid extract. The dietary experiment has not as yet produced any papillary lesions but is being pursued. By the injections of toxin we learned two interesting facts: first, that the kidney in excreting the toxin likewise concentrates it to a high degree and second that such concentration appears to occur in the terminal collecting tubules and

causes damage thereto. The administration of parathyroid extract has apparently caused scattered deposits of calcium in the kidneys of seven of fifteen dogs and in one dog a true and typical calcium plaque lesion was observed.

As our work has clarified the subject in certain particulars, a further word would not be amiss. Let it first be noted that, though renal calculus disease in man is often confused by coexisting complications the problem of origin had best be solved through an understanding of the basic principles involved and a knowledge of the pathology of the simple primary renal stone. Such primary stone, occurring in the absence of other recognized pathologic states of the kidney, is essentially the result of a slow chronic process, and the cause, origin and growth probably cover a relatively long period. It seems proper to point out a glaring fallacy that has been evident in the greater part of the experimental work on this problem, for, aside from the necessary use of lower animals, in almost all the experiments in the past, including those in which calculi were produced, an acute condition was created, by drastic dietary alterations, by extreme overfeeding of certain urinary salts or by establishment of acute infectious processes. Such experiments do not parallel the clinical state or the clinical picture in man, and the conclusions therefrom do not aid in an appreciation of the problem as met in man.

SUMMARY AND CONCLUSIONS

Calcium plaque formation of the renal papilla was observed in 140 of 609 autopsies, i. e., in 22.9 per cent.

In the same series of autopsies forty-nine renal papillae were observed with stone adherent thereto, and in practically every instance the stone was growing from a calcium deposition in the papillary wall.

Stone was found in twenty-five of the 609 autopsies or in 4.1 per cent.

Our efforts to reproduce this calcium plaque formation in lower animals by vitamin-deficient diets failed.

A staphylococcus toxoid was concentrated by the rabbit's kidney from two and one half to sixty times its blood plasma content.

The administration of a stable streptococcus hemolysin leukocidin effects highly suggestive results, causing local damage to the epithelium of the collecting tubules.

After the administration of parathyroid extract to dogs for six months we observed in one renal papilla a calcium plaque identical to that which we have seen in man.

We wish to point out again that the occurrence of renal calculus in man is essentially only a symptom of some underlying pathologic condition of a renal papilla and that its entire development is a slow, chronic process. Acute results obtained in experiments on animals are not comparable to the clinical picture.

LATE RESULTS IN THE CONSERVATIVE MANAGEMENT OF NEPHROLITHIASIS

JAMES T. PRIESTLEY, M.D.

AND

WILLIAM F. BRAASCH, M.D.

ROCHESTER, MINN.

Operation is usually advised and performed if a patient is found to have a renal calculus. For various reasons, however, certain persons who have nephrolithiasis are not treated surgically at the time when this diagnosis is first established. The minute nature of the calculus, the complete absence of symptoms, the presence of serious disease elsewhere in the body, advanced pathologic changes in the urinary tract, and other reasons may apparently render operation unnecessary or undesirable. Some patients who are not operated on progress quite satisfactorily under medical management and no serious symptoms referable to the urinary tract develop. Unfortunately, this is not generally true, as in the majority of cases symptoms of varying severity occur sooner or later and may render subsequent operation imperative or even jeopardize the patient's life.

It therefore seemed worth while to determine, if possible, the factors which influence the clinical course of a patient with nephrolithiasis if early operation is not performed. For this reason a follow-up study was made of 177 patients who had nephrolithiasis but were not operated on at the time when the stones were first discovered. Fifty-seven per cent of these patients returned to the clinic for subsequent urologic investigation, information was obtained by letter from the remainder. Various factors which seemed significant in the progress of these patients were considered, namely, the history of pain in the renal area, the size and location of the calculi, whether the calculi were unilateral or bilateral, the pyelographic appearances, the presence of infection, and renal function.

It should be stated that this series of 177 patients comprises a rather heterogeneous group. In some cases (33½ per cent) operation was advised but was not performed. In other cases (66½ per cent) operation was not advised because it was deemed either unnecessary or undesirable. Some patients had symptomless or "silent" stones, whereas others had experienced severe pain. The entire series, however, is representative of all patients who do not receive early surgical treatment. In a subsequent study further consideration will be given to uniform types of cases.

Most of the patients included in this study were first seen at the Mayo Clinic during the period 1920-1925. The average length of the follow up was therefore slightly more than eleven years. The majority of patients were between 30 and 60 years of age, the average age was 46.4 years. The ratio of men to women was 2:1. There were 131 cases of unilateral and forty-six cases of bilateral renal calculi. Sixteen of the entire series of patients had recurrent stones at the time they were first seen.

A study of all patients revealed that 81.8 per cent of those who had unilateral stones and 97.8 per cent of those with bilateral stones had subsequent symptoms

referable to the urinary tract (table 1). In some instances these symptoms were of sufficient severity to necessitate operation months or years after the calculi were first detected. This occurred more frequently when bilateral stones were present (45.7 per cent) than when stones were present on one side only (35.1 per cent). In the forty-six cases of unilateral stone in which surgical treatment was subsequently required, nephrectomy was necessary in somewhat more than half of the cases, which makes the incidence of nephrectomy twice as high as in a comparable group of cases in which the patients were operated on earlier.¹ In the presence of bilateral stones, surgical treatment must necessarily be conservative and nephrectomy was accordingly performed in only 20 per cent of the twenty-one cases of bilateral stones in which the patients were ultimately operated on, 15.3 per cent of the patients with unilateral stones and 30.4 per cent of those with bilateral stones died within an average of eleven years when "conservative" treatment was employed (patients known to have died of causes unrelated to the genito-urinary tract were excluded).

Certain factors which influence the clinical course of the patient who has nephrolithiasis will now be considered.

HISTORY OF PAIN

Patients who have so-called silent stones have a much better chance of remaining symptom free than those who give a definite history of pain. As will be seen in

TABLE 1—Late Results Following Conservative Treatment of Renal Calculi*

	Cases	No Further Symptoms per Cent	Symptoms Developed Later		Operation Necessary Later per Cent	Mortality per Cent
			per Cent	per Cent		
Unilateral stones	131	18.2	81.8	35.1	15.3	
Bilateral stones	46	2.2	97.8	40.7	30.4	

* Average length of follow up eleven years.

† Deaths from causes known to be unrelated to genito-urinary tract are excluded.

table 2, one third of the patients with "silent" stones had no further symptoms referable to the urinary tract, in contrast to only 33 per cent of those who had experienced pain. The fact that a stone has caused no symptoms for a certain length of time, however, is no assurance that it will continue to remain symptomless, as is evidenced by the fact that symptoms of sufficient magnitude to warrant operation subsequently developed in 24.4 per cent of the cases of "silent" stones.

Although a "silent" stone may be found in an infected kidney which reveals definite pyelographic abnormalities and decreased function, usually there is little or no infection present and the renal function and pyelographic outline are relatively normal if the calculus remains symptomless. Certain cases of large branched stones are notable exceptions to this statement. One should remember however that, in the later stages of renal destruction, pain may be neither so acute nor so frequent. It is difficult to determine why certain stones cause severe pain, pyelographic abnormalities and progressive renal damage and other stones, apparently under almost identical conditions remain symptomless and cause few changes in the kidney. One should

SIGNS OF VITAMIN A DEFICIENCY IN THE EYE CORRELATED WITH URINARY LITHIASIS

A REPORT OF CLINICAL STUDIES AND INVESTIGATIONS ON TWENTY-FIVE PATIENTS

WILLIAM J. EZICKSON, M.D.
AND

JACOB B. FELDMAN, M.D.
PHILADELPHIA

In this study our aim was to determine, if possible, any relationship that may exist between vitamin A deficiency and upper urinary lithiasis in human beings.

In order to prove or disprove such relationship, we decided to test for vitamin A deficiency a group of individuals who have or have had renal or ureteral calculi. The method employed was the dark adaptation

experimental animals were found to thrive or to sicken, depending on the fat content of their diet, whether butter fat or lard. Dietary deficiency in fats could be overcome by feeding green and yellow vegetables.

This led to the discovery of vitamin A and its influence on nutrition. As mentioned, this substance is furnished for the most part by the butter fats.

Moore³ proved that carotene, a constituent of green and yellow vegetables, is a precursor to vitamin A in the animal body.

Capper and his co-workers⁴ found in chickens and Moore³ in rats that the liver fat becomes very rich in vitamin A after liberal feedings of carotene.

It has been definitely proved that vitamin A or its precursor is essential to growth and to normal nutrition and health at all ages. Lack of vitamin A often results in general debility and loss of resistance to infections. Early and frequent manifestations are

xerophthalmia and keratomalacia. The same nutritional deficiency frequently results in the formation of renal calculi.

Wolbach and Howe⁵ and Church⁶ concluded from experimentation that "the specific effect of the absence of fat soluble vitamin A in albino rats, guinea-pigs and humans is found in epithelial tissues. This effect is the substitution of stratified keratinizing epithelium for normal epithelium in various parts of the respiratory tract, alimentary tract, eyes and para-ocular glands and genito-urinary tract."

Friderica and Holm⁶ and Tansley⁷ found that vitamin A deficiency retards regeneration of visual purple, which may explain the connection between shortage of vitamin A and night blindness.

We are particularly interested in experiments demon-

strating the relationship between deficiency of vitamin A and the production of urinary calculi in animals. Among those who have made outstanding contributions to this phase of the subject are McCarrison,⁸ Osborne and Mendel,² Fujimaki,⁹ van Leersum,¹⁰ Perlmann and

Chart 1 (case 7 group III)—C. S., a man aged 38 with a ureteral calculus on the left (diagnosis of ureteral calculus on the right in April 1934) had vision in both the right and the left eye of 6/6. Graphs of photons: A, June 6, 1936, pathologic before treatment; B, April 10, 1937, pathologic after treatment.

or light sensitivity test. In the absence of demonstrable disorders of the eye, an increase in the light sensitivity (dysadaptation) is an indication of the failure of the regeneration of the visual purple. One of the main causes of this condition is lack of vitamin A.

EXPERIMENTAL DATA

The substance or nutritional factor known as vitamin A was discovered through experiments made independently and almost simultaneously in 1913 by McCollum and Davis¹ and by Osborne and Mendel.² Young

Weber¹¹ and Higgins¹² They agree that vitamin A deficiency is often the cause of the production of urinary lithiasis in experimental animals

The effects of this deficiency in the eye are equally well established and cause such symptoms as hemeralopia (night blindness) and xerophthalmia Hemeralopia is due to disturbance in the function of the rods in the retina, concerning chiefly visual purple metabolism

DARK ADAPTATION STUDIES IN UROLITHIASIS

The series reported herewith comprises seventy-five patients, twenty-five of whom had urolithiasis These individuals were subjected to dark adaptation tests by means of a photometer devised by one of us,¹³ which permits of quantitative estimations of dark adaptation and graphic recording of the results

In the following classification, these patients are grouped on the basis of renal or ureteral disorders

Group I Those who have renal or ureteral calculi at the present time and never had any operative procedure for removal of calculi or passed any spontaneously six cases (3, 4, 10, 11, 18, 19)

Group II Those who have renal or ureteral calculi at the present time and have had one or more operations for removal of calculi five cases (1, 9, 12, 13, 24)

Group III Those who have renal or ureteral calculi at the present time and give a history of having passed a calculus spontaneously three cases (6, 14, 15)

Group IV Those who have no renal or ureteral calculi at the present but who have had calculi removed surgically or passed them spontaneously eleven cases (2, 5, 7, 8, 16, 17, 20, 21, 22, 23, 25)

Of the twenty-five patients with urolithiasis, twenty-four were found to have pathologic dark adaptation, varying from mild to severe This group consisted of sixteen white men, eight white women and one Negress, ranging in age from 14 to 62 years Various nationalities were represented and the majority came from the poorer classes

Investigations disclosed dietary deficiency in vitamin A in many instances The remaining fifty patients, constituting a control group, were known to be free from urinary calculi and either were normal or had extra-urinary lesions such as cholecystitis, cholelithiasis or gastric ulcer

None of the patients in either group had eye lesions that might influence the test With few excep-

tions the dark adaptation test in the control group proved negative Exceptions were noted in the following cases myxedema, one, juvenile diabetes, one, jaundice, two

TREATMENT

The twenty-four persons who showed pathologic dark adaptation were then placed on vitamin A therapy The product used was an approved commercial vitamin A concentrate of fish oils The treatment lasted from six to nine months Each patient was given a definite amount of the concentrate ranging from 13,000 units daily (which is held by Eddy¹⁴ and others to constitute the maximum sustaining adult dose) to 52,000 units daily In addition they were placed on acid ash or alkaline ash diets, depending on the urinary pH

The accompanying table shows the amount of vitamin A concentrate administered and the number of

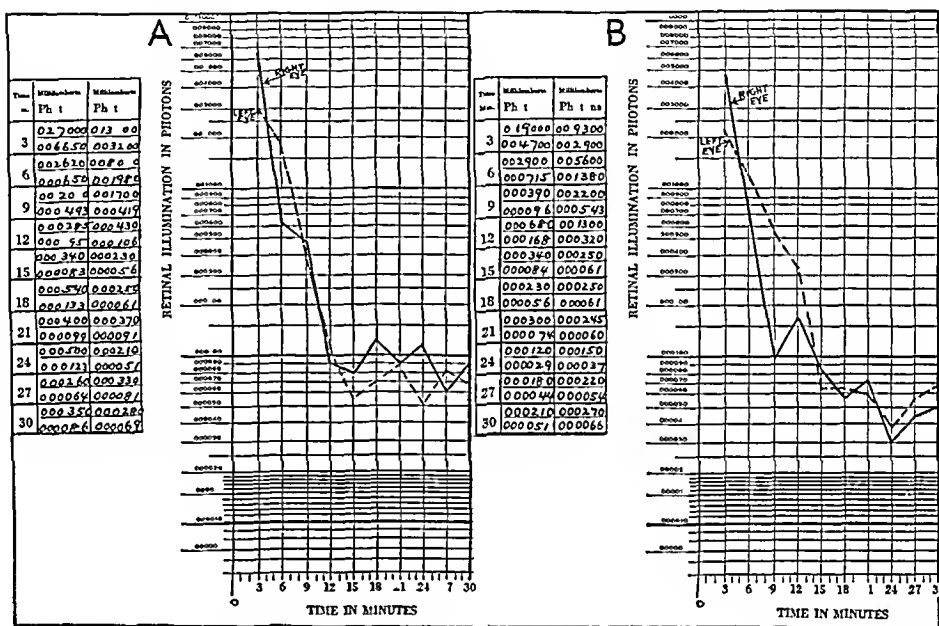

Chart 2 (case 12 group IV)—G I a man aged 46 with a staghorn calculus of the left kidney (uretero lithotomy on the right in 1932) had vision in both the right and the left eye of 20/30—3. Graphs of photons A July 14 1936 pathologic before treatment B March 22 1937 pathologic after treatment

patients who carried out the treatment regularly, those who were treated irregularly, and those who failed to carry out any treatment

Five of these patients had calculi in the kidney and x-ray examination revealed no decrease in the size of the stones

The fact that the effects of vitamin A therapy and a proper dietary regimen, as measured by dark adaptation, were practically nil, is in marked contrast to results reported by others in the treatment of conditions associated with vitamin A deficiency other than urolithiasis. Our observations are in accord with clinical studies reported by the Council on Pharmacy and Chemistry of the American Medical Association.¹⁵ Dark adaptation studies seem to confirm the suspected relationship between vitamin A deficiency and urolithiasis in human beings and to prove the failure of vitamin A therapy to correct pathologic dark adaptation in such cases.

It is possible that ingested vitamin A concentrate is not assimilated or utilized by the body and that the same metabolic disturbance may be the causative factor in urolithiasis.

The phenomenon of dark adaptation is quite familiar. The example of a person walking from the sunny street into a darkened theater and not being able at first to see the seats of the theater clearly is an example of the physiologic function of dark adaptation. Objects in the darkened theater become clearer, depending on the stay of the patient in the dark, i. e. in relative proportion to the regeneration of visual purple in the eye. The visual purple, it has been shown, functions by virtue of the vitamin A it contains. The study of dark adaptation could therefore be used to test the vitamin A in the system. Two factors must be taken into consideration, however, in a scientific study of vitamin A. First, the pupils of all patients must be equal, so as to allow an equal amount of light to enter the eye in all the cases studied. Second, all patients must be examined ophthalmoscopically to make sure that there is no disease of the choroid or deep retinal structures of the eye, since either of these will give a pathologic reading and may be misinterpreted as a vitamin A deficiency. The instrument that we used exactly simulates the phenomenon of entering the movie theater. The sun-lit street is artificially accomplished by the patient being light adapted for the same time in all cases. The dark adaptation is measured in milliamperes and photons by readings taken in absolute darkness, at various minute intervals. Graphs are made so as to compare results of one case with another easily.

SUMMARY AND CONCLUSIONS

- 1 Ninety-six per cent of the cases of renal urolithiasis were associated with vitamin A deficiency
- 2 Vitamin A deficiency was determined by the dark adaptation test with the Feldman technic and instrument
- 3 Twenty-four patients who showed this deficiency were given vitamin A concentrate varying from 13,000 units to 52,000 units daily over a period of from six to nine months
- 4 Of fifteen patients who returned for restudy, fourteen continued to show pathologic dark adaptation and only one showed improvement
- 5 This clinical study corroborates the results of investigations made on experimental animals so far as

the relationship between vitamin A deficiency and the pathogenesis of lithiasis of the upper urinary tract is concerned. It shows, however, that the beneficial effects of vitamin A therapy in experimentally produced urolithiasis in animals cannot be obtained in human beings.

6 The study shows that vitamin A deficiency in human beings with urolithiasis as measured by dark adaptation is influenced little if at all by vitamin therapy.

7 The patients improved in general health, and in no instance has an existing calculus increased in size or a new one formed while the patient was under regular vitamin A and appropriate dietary treatment.

8 The study seems to prove that vitamin A deficiency occurs in association with renal lithiasis but that such deficiency is dependent on lack of assimilation or utilization of this substance rather than on dietary deficiency.

9 This suggests the possibility that lack of vitamin A assimilation or utilization and urinary lithiasis may have a common metabolic basis.

2100 Walnut Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. RANDALL, EIMAN AND LEBERMAN, DRS. PRIESTLEY AND BRAASCH AND DRS. EZICKSON AND FELDMAN

DR. LEON HERMAN, Philadelphia. The observations of Dr. Randall and his associates are undoubtedly important. I understand that one theory in explanation of the subepithelium, extratubular deposits of calcium is that they result from an irritant contained in the urine, the concentration of which increases as the result of tubular reabsorption of water. It would seem that the effects of such irritation should be expended on the epithelium of the excretory ducts rather than on the subepithelial area. It seems to me more reasonable to attribute these formations to a blood-borne irritant, the problem appears to be a biochemical one. The work of my associates on vitamin A deficiency is also of importance. Dr. Feldman is well known among ophthalmologists for his studies in dark adaptation in diseases of the eye. Dr. Ezickson suggested that we ask Dr. Feldman to test some of our cases of urolithiasis, and the results of these studies have been analyzed today. Ninety-six per cent of patients with upper urinary lithiasis show marked loss of dark adaptation, while control cases are normal. They have shown further that this loss of dark adaptation cannot be corrected by vitamin A therapy. This is contrary to results obtainable in other conditions, especially in children, characterized by loss of dark adaptation. These results would seem to me to indicate that there has been a lot of loose talk about the value of vitamin A therapy in urolithiasis. The authors have suggested that lithiasis and loss of assimilation of vitamin A may have a common genesis. If we were able to explain inability of the stone-bearing person to utilize dietary vitamins it would in all probability do much to explain the genesis of stone.

DR. LINWOOD D. KEYSER, Roanoke, Va. A logical approach to the genesis of calculi demands a rigid differentiation of established facts from hypothetical considerations. It is known that excessive feeding by direct or indirect means of calcium oxalate or of calcium carbonate to animals produces stone, that calcium carbonate stones form at times in ulcer patients on intense alkaline calcium rich diets, that at times urate stones are associated with excess urate excretion, that hyperparathyroidism produces excessive urinary excretion of calcium phosphate and calculi. The term 'hyperexcretion calculus' more aptly describes this mechanism than vague references to metabolic error. Yet all the evidence is against hyperexcretion as the sole or even the most frequent cause of stone disease. Again it is known that biologically specific stone forming bacteria exist and after isolation from patients can be made by local or focal infection to reproduce calculus in animals, that alkaline infection is a frequent but not at all consistent accom-

paniment of stone as seen clinically. Experimentally, I have shown that the mechanism is an encrustation of necrobiotic epithelium with lime salts. Likewise quasiserial sections from calical tissue adjacent to stone in human beings shows lime salt deposition in and on the surface epithelium. Dr. Randall's remarkable anatomicopathologic demonstration of lime impregnated papillary plaques on the renal papilla is in line with this observation and a more detailed delineation of this encrustation mechanism. Also it is known that extreme vitamin A starvation will produce stone in animals. The mechanism here is also one of encrustation. These are the known facts. Beyond this knowledge our reasoning is speculative. Little evidence exists to show the relative incidence of hyperexcretion, of infection and of vitamin deficiency as the cause of stone in a given series of cases. The urinary colloids, the relative saturation of different salts in the urine, the acid-base reaction, and the temperature are variable agencies in the urinary solution mechanism. Disturbances of these factors singly or in combination as a probable cause of calculus remain to be disclosed. Most urologists have been disappointed in their efforts at dissolving calculi. It is true that soft carbonate or phosphatic masses do disintegrate at times on acidification of the urine with diet or drugs. Isolated cases of dissolution of urate and of cystine calculi by alkalization are recorded. Yet carefully controlled series of cases such as those reported recently from Dr. Beer's clinic show how far we are at the present time from possessing any type of therapy for consistently dissolving urinary calculi. Stone is still an object for surgical or instrumental removal in most instances. In prophylactic effort against recurrence, analysis of the calculus, appropriate change of the urinary reaction, elimination of infection and urostasis, together with correction of demonstrable metabolic error, are measures which will frequently, but not as often as we might desire, prove efficacious.

DR. JOHN H. MORRISSEY, New York. There is a considerable difference in the scientific approach to a clinical problem on the part of the urologist as compared with other specialists. Here the patient scientific investigator, untroubled by the cares of surgical practice, calmly attacks the problem and correlates his work with the observations of the clinician. But in urology it would seem that we do not hesitate to plunge headlong into a most complicated chemical, bacteriologic or physiologic problem and in a short time we know the cause and cure for every problem—urolithiasis most lately among the list. All this work, utterly unproved and uncorroborated by clinical investigators elsewhere than in these research centers, has done two things: complicated the clinical problem for the urologist and allowed in too many instances the patient to have the decision as to whether the stone should be dissolved, dieted out, or whatever may be the latest method that he has read about. Renal lithiasis experimentally produced in a couple of rats or guinea pigs is one thing. To apply freely the conclusions reached thereby to a human being is another. Urology more than any other specialty has rushed into print on its new ways, and I only have to cite hexylresorcinol, now available in tooth paste, among numerous remedies as examples of our discarded therapeutic procedures once loudly hailed and now forgotten. The problem for us is what to do with the patient with a renal stone too large to pass. The answer to my mind is removal of the stone by a competent surgeon. In the City Hospital in New York over a two year period we have been totally unable to influence the reduction in size or the disappearance of a calculus by any method, and a recent painstaking study by Dr. Pollack in Dr. Edwin Beer's service at Mount Sinai in twenty-six cases of stone produced absolutely no results along the line that we have been led to believe might be obtained and as being in the realm of possibility. In fact the stones in several of these cases increased in size. These results have been confirmed by others. To my mind there is no such thing as a silent stone. Sooner or later that stone will be heard from. The lithiasis patient should be thoroughly apprised at the outset as to his condition and not misled by what a diet has done to white rats. He should be made to understand that he has a problem which ultimately will be handled surgically. I have five patients at the moment with bilateral lithiasis who I hesitate to say are practically directing the conduct of their own cases. They know more about the various preparations of mandelic acid than I do.

Two of them have traveled to Cleveland for consultation and have availed themselves of an opinion from Baltimore. The indication in each of these cases is clear cut, yet they prefer to temporize, and I cannot convince them that they should consider operation at this time. May I suggest therefore that we label our researches in this important field as wholly experimental and speculative rather than clinically conclusive. In this way we shall render a greater service to the sufferer from stone rather than confuse his mind so that he delays radical treatment until infection has set in and the kidney has undergone destruction.

DR MILEY B. WESSON, San Francisco. The presentation of Drs Priestley and Braasch is sane and is based on a study of a sufficient number of personal cases to make the conclusions authoritative. There is no relationship between the severity of the pain and the size of the stone. It is universally agreed that a kidney calculus is potentially dangerous, but there are instances of stone in sterile urine in which, for various reasons, conservative procedures must be followed. In such cases the patient should be given an appropriate diet and mouth medication consisting of an acidifying agent (ammonium chloride, ammonium nitrate, mandelic acid) with methenamine in an attempt to dissolve the stone and ward off infection. At regular short intervals the voided urine should be examined for the presence of infection, and excretory urograms should be made to rule out beginning destruction of the kidney. There are three types of cases of stone too large to pass spontaneously: (1) those in persons whom we can honestly urge to submit to surgery, (2) those in which stones have reformed immediately after surgery and the subjects want assurance that if they submit a second time a third operation is not around the corner, and (3) those with silent bilateral pyonephrosis and staghorn calculi. Some authorities have reported the disappearance of stones under appropriate medication. Drs Priestley and Braasch have done in their series and my experience is in conformity with theirs. Some stones remain in statu quo for many years in an uninfected kidney. Several years ago one of my colleagues heard of a man, aged 43, who was reported to have "milk in his urine." Eventually he met the patient and found that his urine was filled with pus and not chyle. The patient had had a 2 cm stone removed from his right kidney in Auckland, New Zealand, in 1912 and had had no pains referable to the genito-urinary tract since that time. I found urethral strictures. Seventy cubic centimeters of thick pus was aspirated from the right kidney and 55 cc of hazy urine from the left. No phenolsulfonphthalein was excreted in twenty minutes and no neo-iopax in thirty minutes. The pyelograms were made by injecting 80 cc of 20 per cent iopax in the right kidney and 65 cc in the left. Last week his kidney function was as follows: Intravenously injected phenolsulfonphthalein appeared on the right in four minutes and on the left in seven minutes. The differential phenolsulfonphthalein test on the right was 10, 8, 8, 5, 4, 2, or 37 per cent, in one and a half hours, and on the left 10, 6, 4, 3, 2, 1, a total of 26 per cent in one and a half hours. The man is in apparently perfect health and working hard. He has not had any subjective symptoms related to his kidneys in twenty-five years and of course is not interested in more surgery. I believe this case report belongs with Drs Priestley and Braasch's silent renal calculi series, and I want them to tell me what to do with the patient.

DR STANLEY R. WOODRUFF, Jersey City, N. J. The size of the stone is of great significance, as bearing on the treatment, in view of the fact that a very small calculus in the kidney gives rise to few symptoms and little or no infection. The urologist should make several efforts at dislodgment of a small stone by suitable renal lavage before considering surgical removal. The greatest contraindications for operation when minute calculi are diagnosed are, first, the difficulty of making an accurate diagnosis, and, second, the possibility of not being able to find the small particle when operating. One is quite able to mutilate a kidney more in a few minutes by searching for a small nodule of calcareous material than by allowing it to lie in a kidney for several years. The relationship of renal function to late results has been ambiguous, according to my experience. This relationship may be difficult to explain. Often one finds the function of a kidney to be nil in the presence

of a calculus, but on removal of the latter there is a reestablishment of function to a normal output. It has been my custom to pay not so much attention to the actual function of a kidney, deciding treatment rather on the pyelographic examination. This has appeared to me to give a truer picture of the actual functional possibilities of the kidney, for I have noted on numerous occasions when little or no dye was excreted that pyelography showed practically no pelvic change. One can well expect in such an instance that the removal of a calculus will be followed by a return of functional capacity to probably the normal percentage. I do not believe that a stone is silent as often as one thinks. One expects that the only symptom a patient is going to complain about is pain, and the public expects to find this pain to be of an agonizing character. Most urologists will agree that the so-called renal colic is nearly always due to a dislodgment of a stone into the ureter and that the usual pain from a stone in the renal pelvis is more of the dull, aching character, except when it happens to plug the ureteropelvic junction. However, in patients with a renal calculus, a more or less pathologic urine is usually present, and in view of the fact that according to my experience indigestion is the most frequent symptom of renal calculus, these two symptoms may be screaming at one in the presence of the so-called silent stone.

DR HENRY SANGREE, Philadelphia. The major conditions now concerned in the production of calculi appear to center around the infective theory, the dietary theory and some unknown change in the cytoplasm of the cell or the "gerust" substance of the cell. Any one making a careful study of the calculi obtained from one's own series is astonished at the diversity of composition of different calculi obtained from the same kidney and the number of different components in one calculus. In an attempt to analyze a calculus one first examines it carefully with a hand lens, and often a small facet showing the original point of attachment to the renal papilla will be identified. The next step is to roentgenograph the stone to determine its density of shadow, an excess amount of calcium causing a greater density. If the stone is over 5 cm in diameter it should be sectioned, as a better roentgenogram will be obtained when it is of the same diameter throughout. The next procedure is to section the stone through the radius, if possible, and examine the separate layers or concretions formed in building up the calculus. The analysis of individual layers may show different components. If the calculus is of soft or friable material, as in a phosphate or urate stone, it is first mounted in Wood's metal, which will allow section of the stone without its destruction. If any small crystals are present they are examined under polarized light and also, by means of a goniometer, their crystallization system is determined. All patients who form and pass calculi should have a careful check of their parathyroids and tests of the calcium, phosphorus and uric acid content of the blood. A test of the voided urine for cystinuria is routine, and eye-ground examination for avitaminosis is requested. Any obstructive condition such as stricture of the urethra, ureter or ptosis of the kidney is diagnosed with pyelography and urography and treatment is instituted. In a paper previously reported I showed an incidence of 12.5 per cent of stones present in fused kidneys. This is considerably higher than the routine occurrence of calculi in kidneys seen at autopsy, and as histologic examination of the specimens revealed nephritis to be present in 80.5 per cent of fused kidneys, this examination would certainly support the infective theory of calculus formation. Biochemical research and physiologic investigation correlating with clinical examinations will determine the future solution of the problem of the origin and prevention of renal calculi.

DR ALEXANDER RANDALL, Philadelphia. I have been asked by Dr Hepler whether or not we examined the blood calcium in our dogs who were on administration of parathyroid extract. It was done weekly. It is rather hard to raise the blood calcium in a dog, it is even harder to hold it elevated, but we have been able to make the calcium go up to from 12 to 14 mg per hundred cubic centimeters in three dogs. The maximum has been 17, 18 and 19 mg, but they might be, in the next week, down to 11. Our entire effort has been to take the subject of renal calculus out of the mystic and theoretical and

to show that it is but a symptom of some basic preexisting renal disturbance. We have been able to show a precalculus lesion of the renal papilla which is definitely associated with the growth of stone. As soon as the physician grasps the simple, hard fact that renal calculus is but a symptom of some preexisting lesion, the knowledge of the origin and growth of renal stone will have been furthered tremendously and it can then be expected that a logical understanding of prevention will be possible.

DR. WILLIAM J. EZICKSON, Philadelphia. Those who are interested in seeing the clinical details concerning the operations and those who passed calculi spontaneously, many having a history of calculi over a period of ten or twelve years, will find all these detailed analyses and charts and graphs in the exhibit and we shall be pleased to show you all these charts before and after treatment.

THE ACTION OF THEOPHYLLINE WITH ETHYLENEDIAMINE

ON INTRATHECAL AND VENOUS PRESSURES IN CARDIAC FAILURE AND ON BRONCHIAL OBSTRUCTION IN CARDIAC FAILURE AND IN BRONCHIAL ASTHMA

JAMES A. GREENE, M.D.

W. D. PAUL, M.D.

AND

A. E. FELLER, M.D.

IOWA CITY

It has been definitely established that theophylline with ethylenediamine has a favorable influence on the dyspnea of cardiac failure.¹ These results have been attributed in part to the effect on the coronary and cerebral circulation. The present investigation was undertaken in the hope that further information might be obtained relative to the action of the drug in cardiac failure. We are concerned with the effect of the intravenous administration on the intrathecal and venous pressures and on bronchial obstruction.

In the study of the intrathecal pressures the patient was placed on the side in a horizontal position with the head supported by two pillows. The puncture was made in the lumbar region and the pressure recorded by a water manometer. Pressure applied to the cervical veins before and after each study always produced a temporary increase in pressure.

The venous pressure was measured by a modification of the method described by Hussey.² The apparatus consisted of a three way stopcock with a 22 gage needle attached to one opening, a glass manometer to another and a 30 cc syringe to the other. The needle, manometer and syringe were filled with 3 per cent sodium citrate solution. The system can be kept practically free of blood by proper manipulation of the stopcock and accurate measurements obtained for long periods. The pressures were obtained from the median basilic vein with the patient in the supine position and were

recorded in millimeters of 3 per cent sodium citrate solution. The arm remained at the same relative position to the heart during the period of study, but it was not always at the level of the right auricle.

The vital capacity was measured by the usual method before and at fifteen and thirty minutes after injection of the drug.

These studies include observations on the intrathecal pressure alone in five normal subjects, fifteen patients with hypertension and arteriosclerosis without evidence of cardiac failure, six with congestive heart failure due to arteriosclerosis and hypertension, and four with intracranial lesions producing elevation of intrathecal pressures but with normal cardiovascular systems. Observations on the venous pressure alone were made in five normal subjects and in nine patients with congestive cardiac failure. In six patients with cardiac failure the effect on the venous and intrathecal pressures were measured simultaneously. Finally the effect of intravenous administration of the drug was observed on the bronchial obstruction in five patients during an acute attack of bronchial asthma associated with chronic pulmonary disease and in eleven cases in which the asthma was on an allergic basis.

The drug was given in doses of 0.48 Gm. diluted to 30 cc with physiologic solution of sodium chloride and from three to five minutes was required for the injection. Frequent measurement of arterial pressures showed no significant alteration in either systolic or diastolic pressures and no change in cardiac rate was noted in frequent electrocardiograms.

RESULTS

The results of the study on intrathecal pressure alone are summarized in tables 1, 2, 3 and 4. It is to be noted that a reduction in the pressure occurred in each

Time of onset and degree of reduction of venous and intrathecal pressures in a patient with congestive cardiac failure and Cheyne-Stokes respiration. It is to be noted that restoration of normal breathing coincided approximately with the maximum decline in the pressures.

instance. The effect reached its maximum after the injection of from 20 to 25 cc of the solution and coincided with the onset of the relief of dyspnea (cases 2, 4 and 6, table 3), and with restoration of regular breathing in those with Cheyne-Stokes respiration (case 5, table 3, and case 3, table 4). It is to be noted from tables 5 and 6, which summarize the results of the study on venous pressure alone that the pressure fell in all cases of cardiac failure. The maximum effect also coincided with injection of from 20

to 25 cc of the solution and with onset of relief of dyspnea (cases 2, 4, 6 and 7, table 6) and restoration of regular rhythm (cases 2, 5 and 9, table 6)

The observations on the simultaneous measurement of intrathecal and venous pressures are summarized in table 7. These show a close correlation as to the extent of the effect. The relation of time of onset and the character and degree of reduction of the two pressures are illustrated in the accompanying chart. In five of the six patients there was a very obvious relief from dyspnea. One remarked, "The position and needles

were very uncomfortable but it was worth it", another, "I have not been able to breathe so easily in weeks." In the one case presenting Cheyne-Stokes breathing regular rhythm was restored. The respiratory distress was ameliorated in these patients from four to twenty-four hours.

Symptomatic relief occurred in all cases of asthma, as will be noted in tables 8 and 9 and the vital capacity increased in nine of eleven instances.

COMMENT

These studies show that the improvement in dyspnea and the conversion of periodic breathing to a regular rhythm in cardiac failure are related to the decline in intrathecal and venous pressures produced by the intravenous administration of theophylline with ethylene-

diamine. Harrison³ noted a temporary improvement in respiratory distress in cases of heart failure following removal of cerebrospinal fluid. He also observed a parallel decline in venous and intrathecal pressures which corresponded in general to the extent of recovery from cardiac failure. Loman and Myerson⁴ report a reduction in intrathecal pressure in normal subjects following the administration of caffeine.

There is a difference of opinion regarding the importance of the elevation of cerebral venous and intrathecal pressures in the production of dyspnea and orthopnea in cardiac failure. Harrison³ found that the intrathecal pressures measured from the cistern were greater in the horizontal than in the sitting position and sug-

gested that the increased pressure in the former position is a factor in the production of orthopnea. Ernstene and Blumgart⁵ called attention to the parallelism between orthopnea and the elevation of venous pressure. They concluded that the latter reduces the circulation to the respiratory center and thus contributes to the production of orthopnea. Calhoun, Cullen, Harrison, Wilkins and Tims,⁶ on the other hand, doubt that the increase in cerebral venous pressure is a factor in the production of dyspnea or orthopnea. They were unable to produce respiratory distress in normal subjects or to increase it in cases of cardiac failure by an elevation of the cerebral venous pressure by partial obstruction of the cervical veins.

Our observations confirm those of Harrison³ relative to the close relationship of the increased venous and intrathecal pressures in cardiac failure and the observation that a reduction in these pressures has a favorable influence on the dyspnea. They show also that this effect may be produced by the intravenous administration of theophylline with ethylenediamine. Moreover, this drug ameliorates the bronchial obstruction in both bronchial asthma and cardiac failure.

These results provide further information regarding the effect of theophylline with ethylenediamine in cardiac failure, but the mechanism of the action, except for that on the heart, is not clear. It is hoped that the studies now in progress may throw additional light on the subject.

SUMMARY

The effect of the intravenous administration of theophylline with ethylenediamine on the intrathecal and venous pressures, measured separately and simul-

taneously, has been studied in normal subjects, in patients with cardiac failure and in patients with cerebral lesions. The effect on bronchial obstruction has been studied in patients with bronchial asthma associated with chronic pulmonary disease and in patients in whom the asthma was on an allergic basis.

TABLE 9—Change in Vital Capacity and the Symptomatic Relief Obtained in Patients with Allergic Asthma When Aminophylline Was Injected Intravenously During an Acute Attack

Number	Vital Capacity Before Aminophylline Liters	Vital Capacity 15 Minutes After Aminophylline Liters	Subjective Relief
1	0.2	0.6	Yes
2	4.6	5.6	Yes

10			Yes
11			Yes

* These patients also had pulmonary emphysema secondary to allergic asthma of many years duration.

The results show a correlation between elevation of venous and intrathecal pressures in cardiac failure. Furthermore, relief of dyspnea or restoration of regular rhythm in Cheyne-Stokes breathing is related to the decline observed in intrathecal and venous pressures following intravenous administration of theophylline with ethylenediamine.

Finally, theophylline with ethylenediamine has a favorable action on bronchial obstruction both in bronchial asthma and in cardiac failure.

ABSTRACT OF DISCUSSION

DR G. K. FENN, Chicago. Dr. Greene and his associates have pointed out some incontrovertible facts and have left little opportunity for discussion except to speculate on the causes of these phenomena. I am interested in the results because they may indicate improvement in the general circulatory efficiency rather than specific action on the respiratory mechanism. In my work on the coronary circulation I have been impressed with the ability of a deficient coronary flow to produce symptoms of cardiac dysfunction other than angina pectoris or anginal pain. In many instances heart failure has been overcome with no treatment other than that which tends to improve the coronary flow. It is well known that heart failure is invariably associated with increased venous pressure. As the cardiac efficiency improves, the venous pressure falls. Cyster cites a particularly informative case in which the pressure fell, rose, fell and rose in the course of hours during an attempt to convert an auricular fibrillation to normal rhythm with quinidine. This is evidence to indicate that the cerebrospinal fluid pressure follows the venous pressure. Whatever the causes of cardiac dyspnea or Cheyne-Stokes respiration may be, these causes are activated by heart failure, and improvement in the failure results in improvement in the respiratory difficulty. Dr. Gilbert and I have observed in experimental work on the coronary flow tremendous increases in flow, sometimes up to 300 or 400 per cent as a result of injection of the purine base derivatives. These increases are evident in from thirty to sixty seconds after injection. I realize that the intravenous administration of these drugs builds up an effective concentration in the tissues that cannot be duplicated by oral administration and therefore such spectacular results as these would not be likely to be produced by any means other than intravenous injection. My observations would lead to the conclusion that theophylline with ethylenediamine is no better than other members of this group in the production of coronary dilatation.

indeed, it is equal to some others. The ethylenediamine renders the mixture soluble and thus suitable for intravenous administration. This compound appears to be the only one easily available today that lends itself to intravenous injection. It seems entirely possible that the intravenous injection of this compound with its immediate and considerable improvement in the coronary flow may well account for the reduction in venous and intrathelial pressure and the attendant improvement in respiration solely because of the improvement in general circulatory efficiency. If this hypothesis should prove to be correct, it should spur us on to search for some coronary dilator that may be given with equally good results by a less objectionable route.

DR T. R. HARRISON, Nashville, Tenn. Cardiac dyspnea is a complex phenomenon. In patients with Cheyne-Stokes respiration in association with cardiac dyspnea, one of the several factors that may be concerned is an increase in the cerebrospinal fluid pressure, because Cheyne-Stokes respiration is seen in persons without heart disease who have increased intracranial pressure. The results in patients who do not have Cheyne-Stokes respiration but who are more or less constantly dyspneic, or in patients who have paroxysmal dyspnea, have also been good. But I am not certain as to the explanation. It cannot be emphasized enough that these compounds are not only of value in the treatment of edema but are often helpful in the treatment of patients who have little or no obvious edema. I am not certain how that comes about. One of the possible explanations is the increase in coronary circulation. If after administration of a diuretic drug the venous pressure declines as a result of improved cardiac function, it is quite likely that the pulmonary venous pressure will drop also, and this may be responsible for the increase in vital capacity. Another possible mechanism may be concerned in the improvement of the xanthine group of drugs in the absence of marked diuresis. This is loss of edema either in the kidney or in the heart muscle. Such edema does sometimes occur and the heart might very well function better if even a few cubic centimeters of water were lost from the myocardium. Another possible mechanism of beneficial effects of these drugs, although it is hard to see how it could come about so quickly, is diminution in blood volume. One would think that this would not occur unless there was a slight diuresis. My feeling about cardiac dyspnea is that the most important factor in its production is pulmonary congestion. That is by no means the only factor. There are other conditions which aggravate it and which determine whether or not a patient with a given degree of pulmonary congestion will be short of wind. Among those conditions are certain chemical changes that sometimes occur in the composition of the blood, which according to my experience are frequently absent, changes in cerebral circulation, and, quite important, reflex influences from various parts of the body which affect respiration. I would like to state that the person who did the original work on spinal fluid pressure in subjects with heart failure and showed that patients with cardiac failure often have elevated spinal fluid pressure and may be benefited by spinal puncture was not myself but my brother, Dr W. G. Harrison, Jr.

DR ALYAN L. BARACH, New York. I should like to ask whether the authors used this drug in cases of asthma that had become refractory to epinephrine.

DR JAMES A. GREENE, Iowa City. I wish to thank Dr Fenn and Dr Harrison for their very illuminating discussion. With regard to the question whether or not the vital capacity increases in patients with cardiac failure following intravenous administration of this drug, all I can say is that in some cases there is a definite increase. I do not have the figures available. We are studying this phase along with some other factors of respiration in these patients. The mechanism by which the drug relieves the respiratory dyspnea in patients who have a regular rhythm I am not able at this point to say, I don't know. In answer to Dr Barach's question, we have used it in several cases of bronchial asthma which were epinephrine fast and we have obtained very good results in most of them. We have one or two that have not responded to the intravenous administration of theophylline with ethylenediamine but have responded to epinephrine.

IODOBISMITOL IN THE TREATMENT OF SYPHILIS

CHARLES W. BARNETT, M.D.

AND

GEORGE V. KULCHAR, M.D.

SAN FRANCISCO

Iodobismitol contains 6 per cent of sodium iodobismuthite and 12 per cent of sodium iodide. The original solvent, ethylene glycol, has been replaced recently by propylene glycol, and 4 per cent of saligenin has been added as a local anesthetic. Iodobismitol was introduced by Hanzlik¹ in 1932 after prolonged experimental study. The preparation was first used clinically by Mehrtens and Pouppirt,² who reported favorable results in the treatment of neurosyphilis. The rapid involution of both early and late syphilis after the administration of iodobismitol was observed by Strandberg and Sjogren.³ No reports of the use of this preparation in the routine treatment of syphilis have been made as yet.

During the last six years iodobismitol has been used almost to the exclusion of other bismuth compounds in the Syphilis Clinic of the Stanford University School of Medicine. More than 125,000 injections have been given to approximately 3,000 patients. All but 827 of these patients have been excluded from the present study, either because iodobismitol was used simultaneously with other drugs or because less than one full course of twenty injections was given. These 827 patients received a total of 51,655 injections, an average of sixty-two per patient.

Of the 827 patients, 500 were male and 327 female. The ages ranged from 15 to 77, the mean being 39. The males averaged 41 and the females 36. Seven hundred and twenty-nine patients were of the white race, seventy-two were Negro and twenty-six were Oriental. Most patients with early syphilis were excluded because treatment was not started with iodobismitol alone. Four hundred and ten patients were in the latent stage, the duration of the infection in fifty-seven being less than four years. One hundred and two had benign tertiary lesions and thirty-seven late syphilis of the cardiovascular system. Neurosyphilis was present in 284 patients. The involvement was asymptomatic in seventy-six of these and of the meningo-vascular type in thirty. Parenchymatous involvement occurred in 177 patients, 100 having tabes dorsalis and seventy-seven dementia paralytica. The tabetic form of dementia paralytica was included with dementia paralytica. The infection was prenatal in seven patients, all of whom had neurosyphilis. In forty patients more than one form of late syphilis was present. Of these, thirty-nine had involvement of the nervous system, it was associated with benign tertiary lesions in twenty-seven and with cardiovascular lesions in twelve. In one patient with cardiovascular syphilis, benign tertiary lesions were also present.

History of a genital lesion, probably indicating the onset of infection, was obtained from 56 per cent of

From the Department of Dermatology and Syphilis of the Stanford University School of Medicine.

the males and 20 per cent of the females. Fifty-eight per cent of the patients had received no previous treatment, and an additional 10 per cent had been given very little treatment (less than ten injections). Thirty-six per cent had been treated insufficiently (less than one year), and the previous treatment of only 6 per cent seemed to have been adequate.

The iodobismutol was given in doses of 2 or 3 cc intramuscularly, from one to three times weekly, in series of twenty or more, usually alternated with courses of the arsenicals.

A detailed history was taken and a complete physical examination was made when the patient was admitted to the clinic. The examinations were repeated at six month intervals both during and after treatment. In most cases urinalyses were made and the serologic reactions determined at the end of each course, or at approximately four month intervals.

The average period of observation for the 827 patients was two and one-tenth years. One hundred and eighty-seven were followed for more than three years and only forty-three for less than six months. The majority are either under treatment or under observation at the present time.

Treatment was regarded as regular if more than 70 per cent of the scheduled appointments for treatment were kept. According to this standard, 686, or 83 per cent, of the patients received regular treatment.

The effectiveness of treatment was determined by the rate of disappearance of lesions with the patient under treatment with iodobismutol alone, by clinical improvement and by changes in the reaction to serologic tests on the blood and the cerebrospinal fluid.

Since the majority of the patients in this series had late syphilis, infectious relapse was not to be expected. Among the fifty-seven patients with early latent syphilis, this occurred but once, following inadequate and irregular treatment. Relapse in the form of benign tertiary lesions did not occur.

TABLE 1—Changes in the Wassermann Reactions of the Blood Following Twenty Doses of Iodobismutol in 456 Patients with Strongly Positive Initial Reactions

Serologic Response	Type of Syphilis		
	Latent	Benign	Cardiovascular or Syphilis of the Central Nervous System
Number of patients	274	83	99
Unchanged	63%	76%	81%
Improved	20%	13%	13%
Reversed	15%	9%	6%

Data as to the rate of involution of benign tertiary lesions of the skin and bones were obtained in twenty-nine cases. Complete involution of the lesions occurred in an average of twenty-five days with six and one-tenth doses of iodobismutol (122 cc). Wassermann and Goodman⁴ reported the healing of similar lesions with the patient under arsphenamine therapy in about the same period.

A symptomatic response was observed in thirty patients with dementia paralytica and in thirty with tabes after forty or more injections of iodobismutol alone. Of the patients with dementia paralytica, twenty-one were improved, three were unchanged and six

became worse. In the group with tabes, twenty-two were improved, six unchanged and two worse. The satisfactory clinical results observed in patients with neurosyphilis confirm the experience of Mehrtens and Pouppirt. In a subsequent paper a more detailed analysis of the results obtained in the treatment of neurosyphilis with iodobismutol will be reported.

The symptomatic response was determined after twenty or more doses of iodobismutol, usually supplemented by doses of the arsenicals, in twenty-seven

TABLE 2—Incidence of Wassermann Fastness in Patients Treated with Iodobismutol Alone or in Alternation with an Arsenical

Type of Syphilis	Number of Patients	Wassermann Fastness	
		Iodobismutol	Other Heavy Metal Preparation
Latent	230	48%	11%*
Benign tertiary	69	68%	69%†
Cardiovascular and syphilis of the central nervous system	114	69%	

* Moore, J. E., and others: *Cooperative Clinical Studies in the Treatment of Syphilis. The Treatment of Latent Syphilis*. Ven. Dis. Inform. 13: 371 (Oct. 20) 1932 (includes Wassermann relapse).

† Moore, J. E.: *The Modern Treatment of Syphilis*. Springfield, Ill., Charles C. Thomas, Publisher, 1933, p. 272.

patients with aortic regurgitation or aneurysm. Improvement occurred in twelve, thirteen were unchanged and two became worse. Although the number is small, it is interesting that only two of the twenty-seven patients had progression of symptoms during treatment.

Wassermann tests of the blood were made before treatment was started in 806 cases. In 624 the reaction was strongly positive, in 104 weakly positive and in seventy-eight negative. In 456 cases in which the reaction was strongly positive, the tests were repeated after the initial course of twenty injections of iodobismutol. The changes in the serologic reactions are given in table 1.

The effect on the Wassermann reaction of the blood of forty or more doses of iodobismutol without other therapy was noted in sixty-one patients. The majority of these had late syphilis of the cardiovascular or nervous system. The degree of positivity was decreased in 61 per cent, unchanged in 34 per cent and increased in 5 per cent.

Iodobismutol does have some effect in reducing the Wassermann reaction, as shown in table 1, since 35 per cent of the patients with latent syphilis and 20 per cent of those with tertiary syphilis showed improvement after a single course of twenty injections.

The incidence of Wassermann fastness in 418 patients was determined, the majority receiving arsenicals in addition to iodobismutol. A strongly positive Wassermann reaction following one year of treatment, without regard to the intervening reactions, was interpreted as indicative of Wassermann fastness. Intervening reactions were disregarded, since these were sometimes not determined. The data are given in table 2.

The incidence of Wassermann fastness in patients with latent or benign tertiary syphilis is approximately the same as that observed by Moore and the Cooperative Clinical Group. In patients with late syphilis of the cardiovascular or the nervous system, the incidence of Wassermann fastness varies from the 30 per cent reported by Stokes and Busman⁵ for neurosyphilis to

⁴ Wassermann, Harry, and Goodman, M. J.: The Results of Treatment in Late Mucocutaneous and Osseous (Benign Late) Syphilis. *Am. J. Syph. & Neurol.* 18: 59 (Oct.) 1934.

⁵ Stokes, J. H., and Busman, G. J.: A Clinical Study of Late Fast Syphilis. *Am. J. Sc.* 160: 63 (Oct.) 1937.

the 80 per cent estimated by Moore⁶ for dementia paralytica. These variations may be due in part to differences in the sensitivity of the tests used. Although our figure of 69 per cent is higher than that commonly reported, it falls within these limits.

The spinal fluid of 576 of the 827 patients in this series was examined one or more times. At the initial examination the fluid of 52 per cent was normal. Three per cent of the fluids were of type I, 29 per cent of type II and 16 per cent of type III. The classification used was that suggested by Moore.⁷

In 151 cases in which the initial reaction of the fluid was positive, one or more reexaminations were made after various amounts of treatment. The treatment included at least twenty injections of iodobismutol, usually in conjunction with other drugs, but excluded fever therapy. At least six months intervened between the examinations. The changes in the spinal fluid after treatment are compared with the results of the initial examination in table 3.

The reactions of approximately one third of the abnormal spinal fluids were reversed and those of an additional one third were improved after the administration of iodobismutol alone or in conjunction with other drugs, indicating the effectiveness of this form of therapy.

Before each injection patients in this clinic are questioned regarding reactions to the previous treatment. Specific questions are asked concerning nausea or vomiting, diarrhea, abdominal pain, stomatitis, headache, dizziness, chills or fever, pruritus, eruptions and local reactions. The presence or absence and the severity of each reaction are recorded. By this method complaints not due to treatment may be recorded occasionally as reactions. However, by any other method many minor reactions are not detected.

No fatalities from the use of iodobismutol have occurred, although more than 125,000 doses have been given. In only four instances has necrosis occurred at the site of injection, and in at least one of these the reaction was due to local arterial embolism.

The reactions following 43,812 injections of iodobismutol given to 827 patients have been recorded. The

had been given. The lesions were dusky red desquimating plaques, often numerous and in a suggestive aural distribution, but lacked the fawn-colored center and brightly erythematous periphery of pityriasis rosea. Exfoliative dermatitis did not occur.

The most frequent mild local reaction was a burning pain lasting for a few minutes. Less frequently, slight discomfort began several hours after injection and persisted for a day or more. Reactions of these types occurred more often after the first few injections.

TABLE 4—Incidence of Reactions to Iodobismutol

Type of Reaction	Incidence of Reactions (Percentage)
Nausea or vomiting	0.7
Diarrhea	0.2
Abdominal pain	0.4
Stomatitis	0.4
Headache	2.0
Dizziness	0.7
Chills or fever	0.4
Eruption	0.3
Mild local reaction	7.5
Severe local reaction	0.5

Local reactions were classified as severe if the pain was intense or persisted for more than a few days.

On the whole, the reactions to iodobismutol were slight. In only three of the 827 cases was it necessary to discontinue the drug because of intolerance. A total of ninety-three patients experienced no reaction whatever to any of the injections.

In 756 cases routine urinalyses were made before and during treatment, usually at intervals of four months. The urine remained normal in 742. In four patients with evidence of slight renal damage prior to treatment, there was no progression of the renal lesion. The urine became abnormal during treatment in nine cases. In five of these there were moderate amounts of albumin, and in four, granular casts appeared. In no instance did severe renal damage occur.

SUMMARY

The value of iodobismutol used alone or in alternation with the arsenicals was observed in 827 patients with various forms of late syphilis. The rate of involution of lesions, the symptomatic response and the effect on the serologic reactions of the blood and cerebrospinal fluid were determined. Because of its effectiveness and the relative freedom from reactions, iodobismutol is a satisfactory preparation of bismuth for use in the treatment of syphilis.

2398 Sacramento Street

ABSTRACT OF DISCUSSION

DR. M. T. VAN STUDDIFORD, New Orleans. The authors have given a thorough study of their work on iodobismutol and have shown that it has a place among bismuth preparations in the treatment of syphilis. Iodobismutol is absorbed quickly and is also lost quickly. It is therefore harder to keep the bismuth at a certain level. Injections, therefore, must be more numerous than in the water insoluble bismuth in oil preparations. I have used iodobismutol early in syphilis and especially for patients who have had no treatment. I also used it to start off the treatment. Later I have changed to the bismuth preparations, usually subsalicylate. Iodobismutol is less painful than the water soluble preparations and therefore it is quite a good bismuth for the institution of bismuth treatment.

DR. JOHN H. STOKES, Philadelphia. The more one uses bismuth in the treatment of syphilis the more one's respect for properly chosen bismuth compounds increases and the more one believes that in some of the late aspects of the disease it could largely replace the arsenicals. Studies such as those of

TABLE 3—Comparison of the Changes in the Spinal Fluid After and Before Treatment with Iodobismutol, Usually in Conjunction with Other Drugs

Initial Type of Cerebrospinal Fluid	No. of Cases	Reversed	Improved	Unchanged	Worse
II	98	37%	24%	33%	4%
III	53	9%	62%	26%	2%
Total	151	27%	38%	32%	3%

Including two fluids of type I the reaction of both of which was reversed.

incidence of various types of reactions is given in table 4. In many instances more than one form of reaction occurred after a single injection. The number of doses producing reactions therefore cannot be obtained by adding the individual types.

All degrees of oral reaction are included under the term stomatitis. The majority of such reactions were entirely subjective, and only rarely was pigmentation or actual stomatitis observed. The eruptions almost always simulated pityriasis rosea, were usually limited to the trunk and appeared after a number of injections.

⁷ Moore, J. E. *The Modern Treatment of Syphilis*, p. 467.

Barnett and Kulchar should precede and not follow the introduction of the product, and no bismuth compound should be introduced until chemically controlled studies of its rate of elimination form part of the original report. The exercise of adequate controls is difficult, because bismuth is rarely used alone. Even the authors in this excellent study are discussing the action of a bismuth compound used in conjunction with an arsenical, and other able observers have overlooked the same principle. Only by paralleling the alternate use of an arsenical and iodobismutol with the identical alternate use of the same arsenical and another bismuth compound of better known properties can an adequate comparison be made. As a user of bismuth iodine compounds I have a distinct impression that the iodine distinctly steps up the effectiveness of the bismuth. All complex heavy metal compounds used for treatment should be studied as Lomholt studied mercuric salicylate to determine the proportion of the compound eliminated as such, as well as that which was broken down to provide ionic heavy metal for organic combinations within the body. Elimination of the complex unchanged heavy metal molecule may conceivably defeat the antisiphilitic effectiveness of a drug. All discussion of reactivity to an intramuscularly injected drug has an element of technic which makes comparison among different observers almost useless. The single item of massage following injection is capable of changing the entire local reaction report in a series of patients or injections. With well tolerated preparations like iodobismutol, one must watch the temptation to go on and on indefinitely in longer and longer courses, without an adequate knowledge of the rate of elimination. Serologic interpretations of the effectiveness of bismuth I believe involve a distinct peculiarity of the drug. It seems much slower in reversing complement fixation and precipitation tests than does mercury, so that the optimum time to gage the result of a bismuth course is not so much at the end of the course as at the beginning of the next course. This should be recalled in cases of supposed Wassermann-fastness occurring under arsenical-bismuth therapy.

DR HAROLD N COLE, Cleveland. In using a bismuth compound, it depends quite a lot on the preparation in which it is dissolved or in which it is held in suspension. The authors spoke of the fact that these injections were given one, two or three times a week. With the preparations that are dissolved in water, or in one of the solvents like ethylene glycol, we are dealing, of course, with a soluble product, and it is only by studies on excretion in the urine and in the feces, particularly in the urine, that one can be sure about the level of the bismuth in the blood stream, and that is what one is working at. It is not the amount of bismuth that is necessarily deposited in the muscle. What one desires is to achieve a level in the blood stream that will be therapeutic in character and that can be kept at that therapeutic level over a period of time. Otherwise, one may have a preparation, like some of the preparations dissolved in water, in which one has an excretion that will run up to 8 or 10 mg in twenty-four hours and come down just as rapidly, so at the end of twenty-four hours one has practically no therapeutic effect as far as bismuth in the blood is concerned. On that account there are certain of the bismuth products that must be given at least three times a week, and even then one is not sure of a therapeutic level. In Dr Sollmann's laboratory at Western Reserve we have been studying iodobismutol, and this does seem to be one of those products in which one can have a satisfactory level of bismuth in the blood stream by giving the injections twice a week. Now, of course, that does not always mean a product that can be used in office practice. Generally, one is unable to get the patient to come twice a week, once a week is about as often as he will be willing to make a visit and take his treatment. I should like to ask the authors how long at one time they have given these injections of iodobismutol, and how long they think it will be safe to continue these treatments. Dr Svend Lomholt suggested that a bismuth product, to be effective, would have to contain about 0.5 mg of bismuth per kilogram. I think a better measure of the effectiveness of a product is a study of the bismuth excretion in the urine which would be an indication of its level in the blood stream. And in this study that I have spoken of we have found that with iodobismutol given twice a week we can keep the level between 2 and 4 mg

of bismuth in the urine right along, and I think that is a satisfactory level. Anything above 2 mg in the urine should give satisfactory therapeutic results.

DR PAUL E BECHET, New York. The report by the authors of 75 per cent of local reactions seems high. I have used iodobismutol very considerably, with little or no complaint of pain from the patient, I am referring to private patients, and the injections were administered by myself. In advocating thorough massage, Dr Stokes has stressed a most important point. Equally important is the injection of 1 cc of air, after the iodobismutol injection has been completed in order that the drug may not be spilled into the subcutaneous tissues on the withdrawal of the needle. Both these facts are of course well known but are not practiced as much as they should be, particularly by nurses and technicians.

DR GEORGE V KULCHAR, San Francisco. In reply to the contention of Dr Van Studdiford that iodobismutol closely parallels the water soluble bismuth compounds, in our experience, and from the experimental excretion studies, its behavior closely approximates that of the oil soluble compounds and, following the single injection, bismuth is excreted for more than sixteen days, the peak period being reached about the third or fourth day. Regarding Dr Coles question, we had at the outset of this study a group of patients who were treated three times a week for as long as two years. One of the patients received more than 300 consecutive injections of iodobismutol without any systemic manifestations. We realized that our figure of 75 per cent of local reactions is unusually high, but it is quite explainable since these injections were given by medical students as they rotated through the clinic and were given standing up without any supplementary massage. Furthermore, I think that by our method of asking specifically regarding reactions we probably elicit an abnormally high percentage of local reactions.

Clinical Notes, Suggestions and New Instruments

ACUTE SORE THROATS FOLLOWING EXPOSURE TO SELENIUM

H L MOTLEY, PH D, M D, M M ELLIS, PH D, Sc D, AND
M D ELLIS, A M, COLUMBIA MO

Certain symptoms in man following exposure to selenium have been reported, such as pallor, coated tongue, gastrointestinal disorders, nervousness and garlicky odor of the breath,¹ but no mention has been found of acute sore throat. Hofmeister² found that selenium was eliminated from the body by the lungs, urine and feces in the form of a methyl compound (methyl selenide) which is volatile and gives rise to a disagreeable odor resembling garlic. Acute sore throats have been repeatedly observed in this laboratory following exposure to selenium, especially in the form eliminated from experimental animals through the lungs.

One of us (H L M) had three very definite attacks of sore throat following exposure, another (M M E) had two attacks and the other (M D E) had two attacks. In the case of the latter the attacks were milder than in the first two. The laboratory technician had two attacks of sore throat. The technician was entirely unaware of the condition that had developed in the rest of us or of the nature of the material used and almost a month had elapsed after the last selenium experiment when he chanced to remark that he was glad that we were not working with "the other stuff" (selenium) for it made his throat sore. On questioning he described two clear cut attacks of sore throat following contact with dogs injected with selenium.

The acute attacks of sore throat extended over a period of three or four days and were followed by involvement of the bronchi, resulting in a mild bronchitis which persisted in mild

From the Department of Physiology and Pharmacology, University of Missouri Medical School.
1 Dudley H C. *Am J Hyg* 23: 181 (Jan.), 1936.
2 Hofmeister. *Arch Exper Path u Pharmacol* 33: 193, 1934.

form from one to two weeks. The sore throat was slightly different in nature from an ordinary one, being more irritating, painful and prolonged over the usual time of the acute stage of a pharyngitis in connection with an infection of the upper respiratory tract. Excessive amounts of secretions formed in the posterior pharynx, necessitating an undue amount of spitting. Although the initial watery discharging stage from the nose was shorter than with an ordinary cold, the amount of material raised from the posterior pharynx and bronchi was much increased. Coughing persisted from one to two weeks, gradually decreasing in intensity. There were no pleuritic pains in the chest. In most respects the attack was similar to an ordinary infection of the upper respiratory tract, the outstanding exception being the dogged persistence with which the involvement hung on. The material raised from the bronchi in general was not as foul as that seen in an ordinary bronchitis. All except one of the acute attacks of sore throat followed exposure to the expired air of dogs carrying selenium in organic combination, and this air was exhaled constantly into a small room for periods as long as from three to four hours after intravenous or intraperitoneal injection of sodium selenite. The garlicky odor was quite apparent and easily detected on entering the room where the selenium injected animal was breathing, even though only a small amount had been used.

One of us (H. L. M.) had a very severe attack, almost if not allergic, judging by the speed with which the reaction occurred following the weighing of some sodium selenite. About two and one-half hours after exposure the soreness of the throat was first noticed, and it became progressively worse during the afternoon and reached a maximal intensity some nine hours later. Excessive secretions were noticed after four hours and continued to increase in amount for some twelve to fifteen hours. For a period of about five hours almost continuous spitting was necessary to keep from swallowing the material accumulating in the posterior pharynx. The fluid was not very viscous, being somewhat frothy and foamy. There was some reflex salivation from the marked irritation of the throat. The soreness of the throat lasted for five days and was accompanied after the first day by some running of the nose of a clear watery fluid, which became thicker on the second day and diminished in amount. However, the amount of material raised by coughing continued to increase for four days, being greatest in amount in the morning. The material was not foul smelling and at first was fairly clear, becoming grayish in appearance after the second day. The cold and bronchitis persisted for one full week in rather severe form, slowly subsiding over another period of two weeks before the cough was entirely gone.

All the ill effects were noted when the subjects were exposed to dogs exhaling methyl selenide or selenium in some other organic combination, with the one exception occurring when one member weighed some sodium selenite, this individual having apparently developed a hypersensitivity to the compound. The results obtained on dogs³ correspond to the pulmonary and excessive secretions observed in man. Selenium did not stimulate the secretory activity of the salivary glands in dogs, however, the development of pulmonary edema was a regular occurrence in dogs with marked accumulations of fluid in the lungs, and the trachea became filled with a frothy foamy material with a strong garlicky odor of selenium in organic combination. The secretory epithelium of the turbinates was very active, as shown by histologic sections. A concentration of the dog's blood occurred, as shown by the hemoglobin rise and the increase in red blood cells following selenium injections, either intravenous or intraperitoneal. In the dog, death results from pulmonary edema. Extensive studies on some of the lower forms of the vertebrates, particularly the fishes,⁴ revealed wide upsets in permeability of the tissues, with excessive accumulation of fluid in certain organs.

The subjects of this report are not accustomed to infection of the upper respiratory tract at this season of the year (April,

May and June), especially the occurrence in rapid succession of repeated attacks. Most of the experiments on dogs were performed at this time and the subjects were exposed to the dog's expired air in a small room with poor ventilation. Previously injections of large numbers of rats with sodium selenite had been carried out without any ill effects for over five months, and some of the injections were made every other day. The garlicky odor could be detected in the rat colony, although not nearly as strong as with the experiments on dogs, and the length of exposure was much shorter each time. Since the exposure to organic selenium in the expired air was stopped, no further attacks of sore throat have occurred.

The first occurrences of sore throats were discounted as being due to exposure to selenium, although at the time it was noted that the condition was an unusual one and that the irritation resulted without any known cause. However, with later developments the authors were forced to admit the suggestive correlations and the association of the sore throats and colds with exposure to selenium. The nature of the condition, whether a weakening of the resistance of the posterior pharyngeal wall or a direct action of the compound on the tissue, was not determined.

Although this is a very small series of cases, the results seem clear cut enough to warrant further investigation, particularly the public health aspect in those areas in which selenium occurs in the soil in amounts which may not be large enough to produce immediate toxic symptoms but may result in a general lowering of the body resistance toward respiratory and pulmonary infections. Certainly laboratory workers should take precautions against breathing air containing selenium in combination with organic compounds when working with experimental animals and should use great care in handling selenium compounds.

MODERN TRENDS IN THE TREATMENT OF CANCER OF THE RECTUM AND RECTOSIGMOID

CLINICAL LECTURE AT ATLANTIC CITY SESSION

FRED W. RANKIN, M.D., Sc.D.

LEXINGTON, KY

Since January 1927 I have operated on 578 patients for cancer of the rectum and rectosigmoid. This group, on whom many different types of operation have been done—radical, exploratory and palliative—serve as a background for some conclusions as to the merits of different surgical procedures and their accompanying mortality, morbidity and applicability. At the same time, my experience permits emphasis of conclusions which seem to have been relatively well established during the past ten years and allows me to debate with my colleagues on some of the principles of surgery of the lower gastro-intestinal tract.

It is usual in any field of surgery in which continued and progressive advance is made that experience shows many methods to be useless, many to be useful and a few to be essential as gaged by the test of time, and in this respect the progress of surgical treatment for cancer of the rectum—alone or in combination with irradiation—has been no exception.

Several trends which seem to have been established in recent years with more firmness than is customary for the usual procedure have been evident to surgeons interested in this type of work. The more important

Read in the Surgical Division of the General Scientific Meetings at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 8, 1937.

³ Ellis, M. M., Motley, H. L. and Ellis, M. D. Data to be published, 1937.

⁴ Ellis, M. M., Motley, H. L., Ellis, M. D. and Jones, R. O. Proc. Soc. Exper. Biol. & Med. **34**: 519 (May) 1937.

of these are, first, a tendency on the part of more experienced surgeons to employ radical operative measures, namely the one and two stage combined abdominoperineal resection or perineo-abdominal resection, in a larger group of cases, second, the recognition that an important factor in successful treatment of rectal cancer is group management, with adequate pre-operative preparatory rehabilitation and decompression plus teamwork during the operative maneuver and scrupulous, personal postoperative care, and, third, the revival of local destruction of the growth by a new agent, namely, surgical diathermy.

That one could expect more radical surgical procedures to result from prolonged experience and study of postoperative statistical data is but natural, for while it is apparent that no one maneuver is applicable in all cases it seems evident that in the hands of men of mature experience the widest extirpation is bound to be the choice. Obviously, as in the case of cancer of the breast, lip and other regions, the essential principles of radical removal of the offending growth, with block dissection of the gland-bearing tissues in juxtaposition to it, should yield the highest number of cures over a period of years. Nevertheless, no armamentarium against cancer is complete without multiple types of operation alone or in conjunction with other agents, and when one is dealing with cancer of the rectum it is strikingly evident that such factors as age, coexisting debilitating diseases and general undermining of the physical equilibrium demand even a wider selection of methods than is ordinarily essential in the surgical treatment of malignant growths.

The acceptance of group management with preoperative hospitalization during the rehabilitation and decompression by medical or surgical measures is now almost universal and has proved its worth beyond any peradventure. It is highly improbable that the more radical operations for cancer of the rectum or rectosigmoid will ever become routine except in the hands of experienced surgeons for the very reason that they demand cooperation and teamwork before and after the operation more imperatively than most other types of surgical procedure. A radical and dangerous operative maneuver can be accomplished only by meticulous care in which each member of the team cooperates during all the phases, and such teamwork is the result of long association, earnest effort and openmindedness toward any development.

Many factors have combined to furnish a better understanding of rectal and rectosigmoidal cancer, including not only the problems of treatment but an appreciation of symptoms which ultimately may result in an earlier diagnosis. The diagnosis of cancer of the rectum and rectosigmoid can be made in 100 per cent of the cases provided a careful digital examination or proctoscopic examination, or both, is made as a matter of routine. There is no difficulty in recognizing a single ulcerating lesion of the rectum as a malignant growth in the vast majority of cases. Such a lesion can easily be felt with the index finger if the patient, in the knee-chest position, strains against the examining finger and pushes the growth downward. Rectosigmoidal growths frequently are at too high a level to be felt digitally, but a proctoscopic examination makes possible an accurate diagnosis in every case. There is no difficulty in recognizing the lesion under actual inspection, but biopsy may be done regularly or in cases in which there is a question of the pathologic diagnosis.

One purposefully emphasizes examination of rectal and rectosigmoidal growths in discussing diagnosis rather than symptoms, for there are unfortunately no early pathognomonic symptoms. True, 90 per cent of cancers in this location will at some time during their existence be the cause of blood in the stool or on the stool, and in a large number of cases this will be the first symptom for which the patient seeks advice, but blood in the stool or on the stool means that the cancer has advanced until ulceration has invaded blood vessels and consequently has existed for a considerable period. Perhaps irregularity of the bowel habit is characterized by diarrhea or constipation or alternating periods of the two over a short time, e g, a month or six weeks, is the most characteristic symptom. With this as a danger signal, one should therefore investigate such irregularity in stool habit both proctoscopically and radiologically.

I emphasize the sequence of examinations of the bowel—the proctoscopy on a properly prepared bowel should always precede radiologic examination. Indeed, a growth anywhere within 25 cm of the anal margin can always be diagnosed by proctoscopy, and direct visual examination is infinitely preferable to radiography. However, if the result of proctoscopic examination is negative, x-ray investigation is urgently indicated.

Pain in cancer of the rectum, unfortunately, is late in occurring, is untrustworthy when present and frequently is no index to the age or size of the growth. Until the neoplasm has advanced beyond the local confines or fastened itself to some viscera or nerve trunks, where its existence calls attention to it, pain is usually absent. Irritation of the rectal sphincter, with sacral backache and shooting pains down the hips, is not uncommonly found either with epithelioma of the anal canal or secondary to metastases.

PATHOLOGY

Practically all rectal cancers are adenocarcinomas except those occurring in the anal canal, which are usually squamous cell epitheliomas. Beginning in the submucous and mucous coats of the bowel, they extend intraluminarily or occur as sessile tumors or ulcers which grow toward the peritoneal coat. It is well recognized that extension into the lumen usually is more satisfactory from the standpoint of prognosis than extension toward the peritoneal coat and that usually the papillary or adenomatous varieties of rectal cancer are of lower malignancy than the sessile or ulcerating type.

A third type of pathologic process—the colloidal variety—is seen in about 5 per cent of rectal and colonic cancers. The colloid, which appears grossly as a kind of gelatinous material surrounding the growth and the microscopic picture of which is recognized by the characteristic "signet cells," is probably a defense mechanism. Certainly it is true that colloidal cancers have a satisfactory prognosis but tend to recur ultimately more surely than the average adenocarcinoma.

A knowledge of the type of pathologic process with which one is dealing is important from the standpoint of both prognosis and treatment. While it is uniformly felt that the higher grade tumors are radio-sensitive and less amenable to surgical treatment, it is definitely known that there are many exceptions to this rule. In order to grade the tumor rather than as a diagnostic measure, I have regularly done a biopsy on all rectal and rectosigmoidal cancers for twelve years. As for

any tendency to scatter cancer cells by this biopsy, failure to observe such a tendency has been the rule according to my experience

Having demonstrated in a young patient a high grade growth, I feel that it is frequently advantageous to test the radiosensitivity by an actual application. Perhaps it is for this type of growth that the future will reveal radium alone or in combination with surgical treatment to have its most advantageous use.

The colloidal group of cancers, while notoriously prone to recur after surgical removal, are fairly well established as radiosensitive tumors. Certainly, a knowledge of the type of pathologic process with which one is dealing and the intensity of its activity is desirable before one institutes any type of treatment.

RADIUM

Unquestionably, accumulated data show conclusively that in certain cases cancer of the rectum can be cured by radium and that the number of these cases is slowly increasing. The two great difficulties in connection with the use of radium for these tumors are, first, the inaccessibility of the tumors, 67 per cent of them being at the rectosigmoid juncture, and, second, the lack of knowledge as to which tumor is radio-sensitive. Epitheliomas of the anal canal are better treated by radium than by surgical procedures, but as one advances toward the rectosigmoid, the latter becomes the choice of treatment.

Gordon-Watson, Gabriel, Bowing and others who have had the most experience in the use of radium are unanimous in the opinion that it has a place in the treatment of cancer of the rectum but that the field is a limited one. Its greatest value is as a palliative procedure for inoperable and recurring lesions. With its use bleeding is frequently controlled, the tumor frequently recedes enormously and occasionally so-called inoperable tumors are rendered removable.

Preoperative use of radium, while advocated by some surgeons, is still a most uncertain agent, and more data are necessary relative to its action before it is accepted as a routine. One quite agrees with Sir Charles Gordon-Watson that "in the near future rectal irradiation may be so regulated as to offer as high a percentage of cures, in early cases, as by operation and with less risk, and in a certain number without the inconvenience of colostomy," but such views are the result of a hope that equally good results without the mutilation of radical operation may follow its use rather than of a conviction from past experience that this will be the case.

SURGICAL DIATHERMY

Another recent trend has been the application of surgical diathermy as a method of treating cancer of the rectum. Recently, Strauss and his associates reported a number of cases in which the patient was treated over a period of years by this method, and they are enthusiastic over the end results. Careful scrutiny of their series emphasizes not only that colostomy was necessary in one half of the cases but that the mortality figures approach those for patients presenting the less formidable variety of surgical risks who are treated by resection.

The limitation of diathermy for cancer of the rectum is also emphasized by these workers, namely, that it is not a satisfactory method to apply to rectosigmoidal malignant growths because of the liability of rupture into the peritoneal cavity. This contraction of the scope of applicability plus a normal mortality rate

and the necessity of colostomy, the avoidance of which is the major argument against surgical procedures by many surgeons and the public, seems to me definitely to eliminate this method as a regular treatment for rectal cancer, leaving it among the agencies applicable to a small selected group probably presenting bad risks and having low-lying obstructing growths. Fansler has suggested its utility as a palliative procedure calling attention to the fact that once the obstruction is relieved the patient does regain health rapidly and the growth is favorably influenced.

I cannot help feeling that any type of local destruction of a cancer which does not remove the regional glands as well is open to rather pointed criticism for the very good reason that 46 per cent of all rectal cancers have metastasized to the glands when the patient comes to operation. I would not condemn this method without having some experience with it but have no hesitation in placing it in the category of operations which are applicable to a limited group of cases, and I distinctly disagree that avoidance of a colostomy is a scientific reason for selecting any method of therapy. Furthermore, the method requires special apparatus and certainly extreme care in its application. When it is used as a curative measure, the growth should be completely destroyed (and this is not possible without proper speculums and exposure) and the coagulation carried out thoroughly.

In the past year I have seen two patients who had been incompletely treated by electrocoagulation, in neither of whom complete destruction of the growth had taken place and in neither of whom did even palliation result. If the procedure is carried out incompletely and without proper selection of cases, certainly its establishment as a useful agent in combating cancer of the rectum will not be forwarded.

SELECTION OF OPERATION

That the surgeon who operates on cancers of the rectum must be familiar with a number of operative maneuvers is axiomatic if the extension of the operability curve is to be forwarded consonant with a reasonable hospital casualty list. The majority of cancers of the rectum are cancers of the rectosigmoid, and because of the inaccessibility of this part of the bowel "just too low to attack from above and too high to attack from below," the operations of Miles, Jones, Rankin, Mummery and others, or some of their modifications, are useful in ratio to their individual applicability.

That successful surgical maneuvers yield eminently satisfactory results in treatment of cancer of the rectum and rectosigmoid if radically applied when the growth is in a relatively early stage is incontrovertible. The question of the type of operation cannot be answered so easily. Many considerations, particularly the condition of the patient and the stage of the growth, make it important that attempt by a single standardized procedure is not undertaken but that there are available at least four types of operation. These are, in the order of desirability but not necessarily of applicability, in my hands first, radical combined abdominoperineal resection in one stage, second, radical combined abdominoperineal resection in two stages, third, colostomy and posterior resection, and, fourth, palliative procedures and local excision.

One of the fundamental factors when one is deciding on an operative procedure is the acceptance of colostomy as a part of the procedure. It is a happy reflection that there is less and less opposition by members of the

medical profession to colostomy. One regrets that the development of radical surgical procedures against rectal cancer has been retarded by an unfortunate attitude on the part of surgeons as well as the public toward accepting an uncontrollable anus as a portion of the plan. Just why colostomy should have had the stigma cast on it that has been its lot is not clear to me, for really it is rather a state of mind than an actual infirmity which makes its acceptance most reluctant. Nevertheless, despite certain other trends toward the application of radical measures in the treatment of cancer of the rectum, the vast majority of members of the medical profession, and certainly most surgeons experienced in this line, accept without question the necessity of a preliminary or complementary colostomy. That anything short of a radical extirpation of the gland-bearing tissues adjacent to the growth fails to cure a large percentage of the patients is logical when one reflects that nearly one half of the excised specimens of rectal cancers show glandular involvement. When local measures of necessity must be applied because of the inability of the patient to stand radical operation, surgical judgment is reflected in the selection of a less formidable procedure.

One admits that radical surgical maneuvers on the rectum are mutilating and that the sacrifice of nature's magnificent sphincteric mechanism is unfortunate, but in a campaign against cancer such considerations are negligible if by accepting facts one can demonstrate a most hopeful prognosis. I have no experience with and small interest in operations which leave a sacral anus. I feel that it is a distinct disadvantage that the removal of the mesentery of the sigmoid cannot be done if one makes a posterior resection with a sacral anus and, furthermore, that partial control and daily care of the opening are much more easily accomplished if it is anterior and under inspection.

To place the opening either in the left groin or in the midline wound or to remove the umbilicus and leave it in this hiatus is a matter of individual choice. My own preference is to bring the end of the bowel out through a stab wound in the groin. The two factors that make an artificial anus comfortable are to have a small opening through which the bowel emerges

TABLE 1—*Cancer of the Rectum and Rectosigmoid Mortality and Operability*

576 cases	}	Operability, 71.4%
412 resections		
576 cases	}	Mortality 13%

412 resections	}	Mortality, 11.8%
49 deaths		
104 exploration alone or with colostomy	}	Mortality 15.8%
26 deaths		

and thus prevent prolapse and herniation, and to have it properly placed. Any artificial anus properly made is readily taken care of and is not an intolerable companion, nor does it condemn its host to social ostracism or professional inaction.

In the selection of type of operation for cancer of the rectum and rectosigmoid, the choice lies largely between a combined abdominoperineal operation in one or two stages and the Mummery operation of colostomy and posterior resection.

While I am convinced that it is desirable to do as radical an operation in all cases as is possible—that is, as is compatible with a reasonable mortality—I am likewise convinced that there is a place for the radical

two stage combined abdominoperineal operation as well as for the less radical colostomy and posterior resection. Certain patients who are bad risks can be operated on radically in two stages when a one stage operation would be too formidable a task. For patients over 63 or 65 years of age, the one stage operation is applicable at a considerably higher hazard than the two stage operation.

I am entirely in accord with Dr. Daniel Fiske Jones of Boston, who has done more perhaps than any other man in America to advance surgery of the rectum, in

TABLE 2—*Cancer of the Rectosigmoid and Rectum Mortality for Different Operations*

	Cases	Deaths	Mortality
Combined stage abdominoperineal resection 1	44	2	4.5%
Combined stages abdominoperineal resection, 2	89	8	8.9%
Colostomy and posterior resection	133	10	7.5%
Miscellaneous anterior resection tube re section Harrison Cripps operation local excision etc	162	12	7.4%
	117	27	23%

his statement "I have gradually increased the number of one stage operations and decreased the number of two stage operations, and believe that this should be done as men find their ability to do the one stage operation increasing. I still feel that there are a few cases which I want to do and which are not fit for a one stage operation." Likewise, I believe that about 25 per cent of all patients that are still operable as they appear for surgical treatment will of necessity, because of the gravity of the risk to them, be operated on by Mummery's operation of colostomy and posterior resection or by some two stage radical operation such as Jones's or my own.

With a decided preference for Miles's operation, and employing it as I do wherever I deem it possible, I still find an occasional use for my own operation and more than occasional indication for Mummery's. The important necessity of fitting the operation to the patient—individualization of cases—must never be overlooked.

OPERABILITY AND MORTALITY

Table 1 indicates the mortality and operability curves. It will be observed that the gross mortality was 13 per cent including all types of operation, both resections and palliative types, but this was accompanied by an operability of 71.4 per cent. It is interesting to note that for the 412 resections there was a gross mortality of 11.8 per cent, or a smaller hospital death figure than that for the entire group.

Table 2 indicates the mortality figures for the different types of operation. In the series of forty-four combined abdominoperineal resections done by Miles's technic, there were two deaths. Thus, I feel, is too low a figure to be hoped for in a larger series, but I think it does demonstrate that familiarity with the technic and attention to other details permit one to employ this type of procedure with a satisfactory mortality.

It will be seen that the mortality rate for the combined abdominoperineal operations in one and two stages—133 cases with ten deaths—was 7.5 per cent, as compared with 162 cases with twelve deaths, or 7.4 per cent, for colostomy and posterior resection. The last figure is higher than is customary for surgeons using the colostomy and posterior resection regularly, 5 per cent being about the average. This is explained, how-

ever, by the higher operability curve and the fact that the patients presenting the worst risks who were submitted to resection of any type were operated on by this variety of procedure

It seems obvious from these statistics that the often repeated statement that "no one type of operative procedure is applicable in all cases of cancer of the rectum" is again demonstrated and, furthermore, that when patients present better risks and the surgeon desires to extend the scope of the more radical procedure, it is possible to accomplish combined abdominoperineal resection in one or two stages with a mortality and operability comparable to that for other similarly radical operative procedures for cancer elsewhere in the gastro-intestinal tract

The percentage of operability in any study is just as important as is the hospital death list. Operability is in direct ratio to mortality, and the higher the operability the higher the mortality. Statistical data on end results following operation prove indubitably that a larger number of patients actually do well under the aforementioned scheme than by a closer selection of cases, which gives a low mortality rate but refuses operation to a larger group.

It is difficult to fix inflexible standards of operability because of the individual equation not only in the patient but in the surgeon himself. It seems a reasonable standard of operability to subject to resection all patients in whom the local conditions do not, because of fixation to adjacent viscera or abdominal parietes, render the growth utterly immobile and in whom hepatic metastases are not demonstrable. To this rule I would submit a modification, namely, that there are a few cases in which carcinomatous nodules are palpable in the liver in which, because of the ease of removal of the growth and the ability of the surgeon to remove it with a minimal operative mortality, the growth should be resected, since death due to hepatic conditions is much easier than death due to obstruction and infiltration, which go with an unremoved gastro-intestinal cancer.

Again let me emphasize that in borderline cases the patient should be subjected to resection even at the risk of some elevation of mortality statistics, for until more definite knowledge of other therapeutic agents is developed, surgical extirpation accomplished radically remains the hope of sufferers from cancer in the rectum.

CONCLUSIONS

During the past five years I have found it advantageous in my own practice to make some changes in the treatment of rectal cancer. They are as follows:

- 1 Acceptance of the principle that the most radical type of operation should be applied in all cases in which judgment indicates that such a procedure may be done with a reasonable hospital death list.

- 2 The exertion of every effort to increase the scope of operability to the point of taking in all borderline cases. Other things being equal, I think that only hepatic metastasis and immovable fixation to the parietes or adjacent viscera should eliminate attempts at extirpation. This rule should be modified further in a certain percentage of cases by acceptance for palliative resection of a small group of movable tumors which have already metastasized to the liver.

- 3 Abandonment of spinal anesthesia.

- 4 Employment as a routine of postoperative transfusions and, in cases in which anemia and great debility exist, preoperative transfusions as well.

- 5 Extension of the preliminary preparatory period to at least seven days and insistence that decompression be complete whether it is accomplished by medical measures or by surgical procedure. If on exploration the preliminary measures are found not to have been successful in reducing the obstruction and eliminating a great deal of local infection, it is desirable to do immediately a graded operation, the first step of which usually is a cecostomy.

- 6 The abandonment of the preoperative intraperitoneal vaccination. I do this regretfully, but a study of my private cases the last five years, in which vaccination was not done, in comparison with those which I reported for a previous six year period, makes it impossible for me to escape the conclusion that vaccination is not the large factor in reducing mortality that I thought it to be.

- 7 The employment of presacral neurectomy as a routine in the hope of lessening complications in the bladder. However, it must be admitted that this procedure has failed to achieve as brilliant results as were hoped for.

A statistical study of end results, particularly of the more radical procedures, warrants the assertion that according to the present state of knowledge the choice of treatment for rectal cancer is operation. With an increasing operability curve and a lower mortality rate, this treatment of rectal and rectosigmoidal cancer is rewarded by as favorable a prognosis as that for cancer of the same intensity elsewhere in the body.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS HOWARD A. CARTER, Secretary

SLEEPWELL GOLDEN FLOSS PILLOWS NOT ACCEPTABLE

Manufacturer: Golden Floss Pillow Company, 1216 Harney Street, Omaha

The Sleepwell Pillow is recommended by the company as a "non-allergic" pillow for use by those predisposed to hay fever, asthma, sinus or various allergic skin reactions. The stuffing of the pillows consists of cat tail bloom. According to the firm, "Golden Floss" contains no basic ingredients that can produce irritants to the aforementioned allergic conditions. The filling is not medicated but is guaranteed to be "non-allergic," that is, free from irritating dust. It contains, according to the firm, no cotton, kapok, hair, feathers, wool or down.

The Council appointed an investigator to investigate the two pillows "Sleepwell" and "Golden Floss" and also a bottle of serum for testing allergic reactions. From the character of the material used as filling, seedlike particles, the investigator reported that it was potentially allergenic. He used the extract prepared from this material by the firm to test reactions on a series of patients. They failed to react to the serum.

The investigator made it clear that because a substance fails to react in a number of patients the test does not signify that the substance is free from allergenic irritants. In the case of the material under discussion, he believed that the patients who had come to his attention were not sensitized to cat-tail bloom because they had had no direct contact with it. In his opinion, if such contact is continued, as it would be in the use of the pillows, allergic individuals would become sensitive to it just the same as some allergic individuals became sensitive to kapok when it was substituted for feathers.

A pertinent decision of the Advisory Committee on Advertising of Cosmetics and Soaps may well be included here with

regard to the use of the term "non-allergic" "1 The committee is unable to accept any statement to the effect that a product is nonallergic, allergin free or synthetic nonallergic, because even the simplest preparation may be allergic to a susceptible person

Beginning with July 1, 1937, the term 'nonallergic' shall not appear in the name or description of any cosmetic preparation unless an asterisk appears opposite the word 'nonallergic' accompanied by a suitable notation explaining the limitations of the term" The Council on Physical Therapy voted to impose similar restrictions on the use of the term "non-allergic"

In view of the unfavorable report the Council on Physical Therapy voted the Sleepwell Golden Floss Pillow not acceptable for inclusion in the list of accepted devices

ROSE CW JUNIOR RADIOTHERMY UNIT ACCEPTABLE

Manufacturer E J Rose Mfg Company, Los Angeles

The Rose CW Junior Radiothermy unit is a portable machine designed for medical and surgical use. It comes in a black leatherette carrying case with bakelite panel and metal chassis, weighing approximately 40 pounds. Terminals are supplied for the conventional pad type of electrodes and for electrosurgical instruments, the latter for coagulating, cutting and desiccating purposes.

Rose CW Junior Radiothermy

The CW Junior comprises a tuned plate, tuned grid, push-pull oscillating circuit employing two tubes of a manufacturer's rating of 170 watts maximum attainable plate power output each, and a patient circuit inductively coupled to the oscillator with a variable condenser incorporated in the circuit for tuning purposes. The wavelength is approximately 16 meters.

The input power required to operate the unit at full load is 600 watts. Since no acceptable means has been devised for true measurement of the output in terms of watts, no claims for such are made.

However, a phantom load test by means of electric light bulbs connected through condenser pick-up plates and arranged to activate a photo-electric cell and calibrated meter approximates 275 watts.

The transformer temperature rise and the rise inside the cabinet taken at various levels are within the limits of safety prescribed by the Council. Burns may occur when this unit is being used but are less likely to occur than with conventional diathermy and may be avoided by the use of ordinary precautions.

The firm submitted tests on the heating efficacy of the unit when applied to the living human thigh. Four healthy male medical students were

in the anterior part of the thigh at depths of one eighth inch, three-fourths inch and 2 inches or on the bone. These depths were measured from the skin straight in, that is, normal to the skin surface. The averages for eight observations with the cuff technic are given in the table.

Averages of Eight Observations, Cuff Technic

Deep Muscle		Subcutaneous		Skin		Oral	
Initial	Final	Initial	Final	Initial	Final	Initial	Final
90.3	102.4	98.0	102.4	93.2	99.9	9.3	98.8

The unit was tried out in actual clinical practice by an investigator for the Council and found to give satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to include the Rose CW Junior Radiothermy Unit in its list of accepted devices.

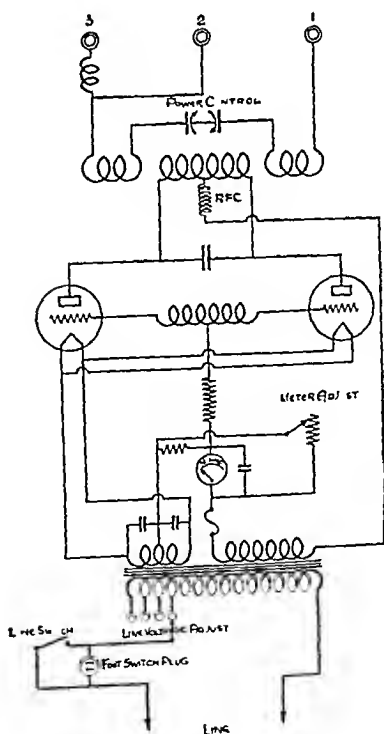

Special Article from the American Medical Association Chemical Laboratory

THE FOLLOWING REPORT IS ISSUED UNDER THE AUSPICES OF THE
A M A CHEMICAL LABORATORY PAUL NICHOLAS LEECH, Director
A M A Chemical Laboratory

ELIXIR OF SULFANILAMIDE- MASSENGILL II

The report on the Elixir of Sulfanilamide-Massengill episode published in the November 6 issue of *THE JOURNAL*, pages 1531-1539, contained a survey map of the deaths to October 29. Herewith the survey map is brought down to date. This shows that there have been seventy-three deaths reported to November 11. As may be seen, all but a few of the reported deaths have been from the Southern states. It is emphasized that the additional deaths reported are not recent but have only recently been reported as having followed the administration of Elixir of Sulfanilamide-Massengill. That no recent deaths have occurred shows the effect of the wide publicity initiated by *THE JOURNAL* and the excellent work of the government in removing the product from the market.

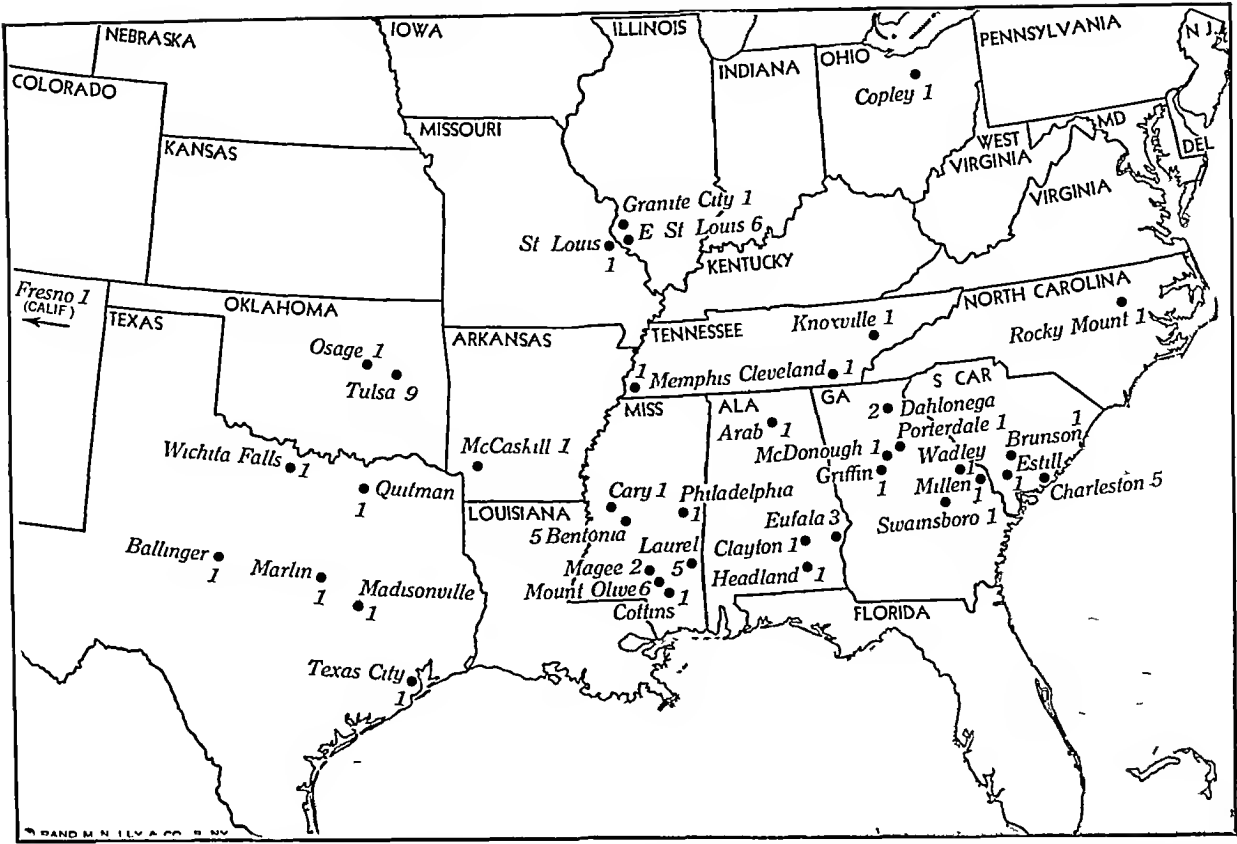

In reports appearing in the newspapers and elsewhere there has been considerable confusion, many of the deaths have been attributed to sulfanilamide, which was not the causative factor. As pointed out previously, the diethylene glycol used in the solvent was the harmful agent. There has been further confusion between the various sulfanilamide derivatives, their properties and names, and the chemical difference between ethylene glycol and diethylene glycol. For the information of physicians there is reproduced herewith a chart, modified from that shown at the last annual session of the American Medical Association with reference to sulfanilamide and its related compounds. Also reproduced is another chart showing the structural interrelationship between ethylene glycol (used in solution as a solvent and an ingredient for antifreeze solutions), diethylene glycol (also a solvent), and dioxane (to which references have been made in toxicity studies). Only diethylene glycol was found in the Elixir of Sulfanilamide-Massengill.

Schematic diagram of circuit.

the subjects. Two tests were run on each making eight observations in all. Temperature measurements were taken with the usual thermocouple technic, a thermocouple being placed

Reported Deaths from Elixir of Sulfanilamide-Massengill

To the best of our knowledge this map shows the deaths confirmed by telephone telegraph or other authoritative communication resulting from the administration of Elixir of Sulfanilamide Massengill up to and including November 11 no responsibility however is assumed for its absolute correctness The city names indicate the residence address or place of death of the victim or the address of the attending physician

A SPECIFIC IN BACTERIAL INFECTION

Chemotherapeutic agents that are active against certain gram negative cocci have been discovered The implications of the discovery are far-reaching Compounds showing activity have the following formulas and the following names have been appended to them in the literature

The confusion in the nomenclature is unfortunate. The pharmacodynamics of the compounds are still unknown. Administration is not without immediate danger and the later effects if any are unknown. Further developments will follow

SATURDAY, NOVEMBER 20, 1937

POPULATION—SUPPLY AND DEMAND

In an editorial¹ entitled "Headed for the Last Census?" published last week it was pointed out that, if the fertility in most countries continues to show the same rate of decrease now evident, a definite loss of population will occur in from approximately five to fifty years. Even though it is not at all certain that this tendency will continue, the possibility must be apprehended. As far as it affects the health and socio-economic life of the country at that time, it should be seriously considered. The Proceedings of the World Population Conference in 1927² and the publications of the Scripps Foundation have already done much to indicate the lines along which further studies should be made.

Burch,³ in the second of two articles on the subject, has reiterated one factor which, if it continues, should be of grave importance in connection with the whole problem. With the psychologic intelligence test as a measure of intelligence, it has been found that, regardless of whether the study involves economic, social, cultural, occupational, educational, intellectual, rural or urban groups in this country, the lower intelligence strata in each group have the largest families and the higher strata the smallest. Although the hereditary transmission of intelligence in some instances seems to follow definite patterns, it does not always do so. While this is alarming at first glance, nature in greater wisdom, possibly, takes this method of restoring some other element which must be constantly replaced. These possibilities, however, are largely speculative, the greater mass of evidence indicates that it is unfortunate that the higher intelligence groups do not replace themselves to at least as great an extent as those of lower intelligence. What effect, however, this fact will have on the future of the country can be only partially imagined.

Numerous effects of the declining birth rate have been pointed out. Thomas⁴ states that a declining population would increase rather than ameliorate unemployment and would make recovery from any future economic depression more difficult. It would be particularly noticeable in the demand for certain capital goods, such as houses, and, with the adaptation of industry to mass production, the shrinking of markets due to falling numbers might necessitate radical revision of methods.

Another effect of the declining birth rate would be alteration of the age composition of the population. In England, according to Thomas, children under 14 form today 23 per cent of the population, with 64 per cent between the ages of 15 and 60, and 13 per cent over 60. If present rates hold for sixty years, only 4 per cent of the population will be under 15, 52 per cent will be workers from 15 to 60, and 44 per cent will be over 60. The effect is already noticeable, according to Martin,⁵ who states that in 1901, 74 per cent of the people were aged 60 and over and in 1931 this percentage had risen to 11.56, an increase of 50 per cent. Accompanying this rising proportion of the elderly, social expenditure will increase, since the burden will have to be borne by a smaller number. There will be an increase, Thomas points out, in invalidity, in the burden of state insurance and in the relative cost of old age benefits. The altered age distribution will necessitate reorientation of the social services with emphasis on accommodation for the aged rather than for the young. Thus there will be less need for child welfare services, hospitals for infectious diseases and schools but an increased demand for accommodation for the senile, the bedridden and the blind. Some of these changes have already become manifest in England, where it is understood that some schools are no longer completely utilized and some of the accommodations for children have passed their maximum employment.

Burch, however, takes issue with some of these conclusions and says that, while probably it is true that there will be an increase in the proportion of persons between 60 and 80, this does not mean that the people in the productive age groups will be overburdened, since there will be a smaller number of dependent children. He says that when the population in this country reaches approximately 150,000,000 at about 1980, there will be fewer dependents as far as age is concerned than at present. This would be true even if persons between the ages of 40 and 65 were considered only half as valuable from a productive standpoint as persons between the ages of 20 and 40. Extreme pessimism, Burch believes, is not justified, since the birth rate in this country need not necessarily follow that of Europe, which is far more densely

populated. Thus, although the decrease in population prophesied is far from certain to develop, it is important to physicians, educators, public health officials, legislators and life insurance companies, as well as to industry, to follow with close attention the developments that occur and to attempt with the help of this foresight to avoid unnecessary complications.

DEATHS FOLLOWING ELIXIR OF SULFANILAMIDE-MASSENGILL IV

Seldom has any catastrophe stirred the United States to the extent to which press and public have been aroused by the needless deaths resulting from the Elixir of Sulfanilamide-Massengill. The repercussions have been varied. Unfortunately, many believe that sulfanilamide was the toxic agent. All the work and confirmatory data reported thus far and transmitted to THE JOURNAL show that diethylene glycol was the causative agent. This does not mean that sulfanilamide is a harmless drug, it is potent and should be used only under the close supervision of the physician.

The number of deaths from the elixir that have been reported since the statement published November 6 has increased from sixty-one to seventy-three as of November 11. The increase in the number of reported deaths does not indicate that the patients died recently, it simply means that reports of additional deaths have been confirmed.

In the publicity, much confusion is apparent in the nomenclature of sulfanilamide and its derivatives and also of certain of the glycols. The Chemical Laboratory reproduces elsewhere in this issue¹ charts pointing out the proper nomenclature and giving the chemical structure of the products.

An interesting sidelight on the tragedy is the Massengill house organ issued under date of October 25, in which Elixir of Sulfanilamide-Massengill plus "corrective mixture"² is suggested for the treatment of colitis. Undoubtedly this was printed in advance of October 25, but it shows the readiness with which products are recommended for various conditions apparently without careful laboratory and clinical tests being made as to value or harmlessness.

Another lamentable feature is the manner in which various businesses involving the use of either diethylene glycol or sulfanilamide are being attacked in uninformed editorials or by whispering campaigns set afoot by competitors who do not hesitate to profit from unanticipated misfortune. Clearly these deaths resulted from overdosage of a toxic agent wrongly used. Such an incident bears no relationship to the proper uses of either of the substances concerned.

Under the present Food and Drugs Act or even under any of the food and drug bills now before Congress, there seems to be no provision which would prevent a repetition of this tragedy. Yet the people have

a right to protection against incompetent or unscrupulous manufacturers. Complete disclosure of formulas on the label might be helpful.

The medical profession has been advised for years concerning the status of new drugs by the Council on Pharmacy and Chemistry of the American Medical Association. Recent correspondence indicates that many of the physicians of the United States are fully aware of the value of this service of organized medicine. However, there are many physicians who do not follow closely the reports which are issued almost weekly. Any pharmaceutical house which desires to market its products honestly and in accordance with the rules of the Council may have its products considered. Remuneration is not accepted in any shape or form for the consideration of products by any of the councils of the American Medical Association. The potential value of the advice of the Council on Pharmacy and Chemistry to the medical profession and to the public is manifested by the fact that it did not accept any brand of dinitrophenol or any "elixir" of sulfanilamide.

Current Comment

NEW YORK CITY SCHOOLS USE A M A BROADCASTS

An interesting use of the American Medical Association and National Broadcasting Company dramatized radio health broadcasts is reported from the Board of Education of the City of New York by Dr. I. H. Goldberger, assistant director of health education. New York's junior high schools and a large number of the senior high schools will take part in a study of the value of enriching health knowledge through such broadcasts as these, sponsored by the American Medical Association and the National Broadcasting Company. The schools will be divided into two groups. Group 1 will listen to the weekly broadcasts until the end of the first semester, group 2 will not. Then both groups will be given an examination on the ground covered in the broadcasts. During the second semester the role of the two groups will be reversed, group 2 becoming listeners and group 1 nonlisteners. The two groups will be examined again at the end of the second semester. Since the broadcasts occur during school hours, there will be no likelihood of nonlisteners listening, except in rare instances, and the groups will be large enough to minimize the effect of such uncontrollable variable factors. The comparative showings on these examinations should give at least a general idea of the value of radio dramatizations in health teaching. Such use of the program is exactly what was hoped for and intended when the program was planned and announced. It would be highly desirable if more school systems would participate in the programs in similar manner. This use of the program might with propriety be called to the attention of local school boards and officials by county medical societies and auxiliaries.

PROPOSALS, PRINCIPLES AND PETITIONS

On November 7, newspapers throughout the United States referred either in extenso or briefly to a series of principles and proposals which were signed by 430 physicians, whose names were released to the press. This was widely heralded as a revolt against the American Medical Association, in most instances the headlines declaring it a definite movement in behalf of state medicine. These principles and proposals with the 430 signatures have been sent also to the secretaries and officers of most of the medical societies—large and small—in the United States, urging their adoption. Since that time the headquarters of the Association has been deluged with letters from physicians throughout the country, some protesting the use of their names, others sending the letters by which they refused the use of their names and still others demanding summary action on the part of the Association. The entire matter is being referred to the Board of Trustees of the American Medical Association, which meets in Chicago this week and which will no doubt issue a statement relative to its point of view. In the meantime, members should realize that the policies of the American Medical Association are established by the House of Delegates, which at the Atlantic City session took definite action opposing most of the proposals here offered. Obviously all proposals should come to the American Medical Association in the regular manner through the state associations and the House of Delegates. Individual physicians will do well to consider carefully the ultimate effect of all such plans and proposals before affixing their signatures.

ALCOHOL AND TRICHINOSIS

Generous quantities of alcohol have been advised on theoretical grounds as a prophylactic measure against trichinosis. Pierce and McNaught¹ of the department of pathology at Stanford University School of Medicine have tested the effects of alcohol in vitro on the digestion of *Trichinella*-infected meat. Rats infected three months previously with trichinae of human origin were killed, skinned, eviscerated and passed through a meat chopper, 5 Gm. samples of the resulting infected ground rat meat were placed in beakers and subjected to the action of 100 cc. of artificial gastric juice, from 9 to 23 per cent alcohol was added to half of the beakers, the other half being diluted with equal volumes of distilled water to serve as controls. After six hours' incubation at 37° C. the meat in the alcohol-free samples was completely digested and all trichinosis larvae were set free in the digestate. At this time the samples containing alcohol showed only partial digestion. The digestion was allowed to continue for eighteen hours, after which each sample was strained through a 60 mesh wire sieve. The undigested meat in each sample was discarded and the number of free larvae in each digestate were then counted. In the alcohol-free controls an average count of 12,732 free larvae was obtained. The alcohol-containing digestates, however, gave counts varying from 2,650 to 7,660, the count decreasing with increases in alcohol percentage. From

these data alcohol may interfere with the liberation of the larvae during the process of normal gastric digestion of infected meat, owing presumably to alcohol inhibition or destruction of peptic enzymes. Effects on tryptic enzymes have not yet been determined. In order to test whether or not alcohol has any direct trichinellacidal action, the Stanford experimenters subjected free and demonstrably viable larvae to concentrations of ethyl alcohol ranging from 0.1 to 25 per cent. Death of free larvae is readily demonstrated microscopically. After six hours' contact with the alcohol no trichinellacidal action was demonstrable even when 25 per cent alcohol was used. After twelve hours, however, the larvae exposed to 25 per cent alcohol were all dead, while those exposed to 12.5 per cent alcohol were still viable. By the end of twenty-four hours the larvae were dead in tubes containing over 62.5 per cent alcohol. *Trichinella* larvae, therefore, are surprisingly tolerant to alcohol, resisting concentrations greater than those maintained for any period in the human stomach. Judging from these data the only prophylactic effects that can be attributed to alcohol are the questionable effects resulting from alcoholic paralysis of gastric digestion.

INFECTION OF LOWER GENITAL TRACT IN YOUNG GIRLS

Reichert and his collaborators² have reported the clinical, bacteriologic and sociological data of 121 girls with infections of the lower part of the genital tract studied over a period of five years. In the course of the study 842 endoscopic examinations were made, 264 cultures were studied and more than 2,000 smears were examined. The technique for obtaining uncontaminated material from the various levels of the lower part of the genital tract was definitely improved. About three fourths of the cases were gonorrheal in origin and about one fourth were nongonorrheal. Thirty-five per cent of the patients in this series were 5 years of age and 50 per cent from 5 to 9. The remaining 15 per cent were from 10 to 14 years old. The onset of the infection reached a peak in May, and there were slightly more cases during the spring and summer than during the fall and winter. The only constant symptom as obtained from the history was the presence of a discharge, which at the onset was profuse, greenish yellow and purulent. The vulva was always involved, the cervix almost always and the urethra in about half of the cases of gonorrheal and a fourth of the cases of nongonorrheal infection. The vagina was involved in 41 per cent of the cases of gonorrheal and in 19 per cent of the cases of nongonorrheal infection. Valid clinical criteria were not found to distinguish between the gonorrheal and the nongonorrheal infections. The differential diagnosis was based entirely on examination of smears and cultures. In more than half the cases of gonorrhea the infection was contracted in the home and in all but one case the source of infection was an adult. A 2 per cent solution of strong protein silver in tragacanth jelly was the most effective preparation for local

application. It resulted in an apparent cure in 80 per cent, with recurrences in 10 per cent. Estrogen was used in treating thirty-two cases, with the frequent result of causing engorgement of the breasts and growth of pubic hair. Although a larger percentage of patients thus treated were apparently cured in a shorter time, there was a higher incidence of exacerbation in this group. In the final analysis the results were similar in the two series. In a small group of patients theelin suppositories were used in conjunction with the local treatment, with results indicating the further reduction in the total amount of estrogen necessary to effect a cure. Since treatment with estrogen should be as restricted as compatible with consistently good results, the use of theelin in oil or in suppositories with adjuvant local treatment in cases in which the infection recurs or does not respond seems to offer the most satisfactory form of treatment for gonorrheal infection of the lower part of the genital tract.

Association News

THE SAN FRANCISCO SESSION

Applications for Hotel Reservations

The Subcommittee on Hotels of the Local Committee on Arrangements has furnished a list of San Francisco hotels and rates for rooms, which may be found on advertising page 55 of this issue of THE JOURNAL together with an application form that may be used to secure reservations through the Subcommittee on Hotels. The form that is printed in the advertising pages may be clipped and, when properly filled in, should be sent at once to Dr. Frederick C. Warnshuis, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, Suite 2004, 450 Sutter Street, San Francisco, Calif.

If those who expect to attend the annual session of the American Medical Association will send in their applications at the earliest possible time, there should be no difficulty encountered in securing satisfactory accommodations. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference.

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs, beginning Oct. 13, 1937, and running weekly through June 15, 1938. The programs will be presented over the Red network each Wednesday at 2 p. m. eastern standard time, 1 p. m. central standard time, 12 o'clock noon mountain standard time and 11 a. m. Pacific standard time.

The dates and topics of the broadcasts for the coming months are as follows:

Hygiene

November 24—Rest, Relaxation, Refreshment: all work and no play, or all play and no rest—bad for health.

December 1—Tuberculosis, Foe of Youth: how bad habits of hygiene and unwise living, plus infection, favor tuberculosis.

Diet

December 8—It Takes All Good Foods: a well rounded diet and how to get it.

December 15—Vitamins, Minerals and Common Sense: more about a balanced diet in special relation to minerals and vitamins.

The stations on the Red network are privileged to broadcast the program but since it is a noncommercial program they are not obligated to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program

director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Personal—Dr. Frederick L. Reichert, San Francisco, received the honorary degree of doctor of science from Franklin and Marshall College, Lancaster, Pa., October 3.

Limit Sale of Sulfanilamide—The California State Board of Public Health, recognizing the dangers that lie in the promiscuous use of sulfanilamide, issued an order September 14 to limit its sale and prevent its unauthorized use, according to the *Weekly Bulletin* October 23. Until more is known of the reactions that it may produce in the patient, its sale is prohibited.

University News—The fifth annual meeting of the Pacific Coast Section of the American Student Health Association will be held at Mills College November 26-27. The program will include a discussion of venereal diseases and their control, student health with reference to tuberculosis, syphilis, typhoid and other diseases, administration of the hygiene of environment, informational hygiene, and the hygiene of physical education activities. Dr. Ruby L. Cunningham, University of California, Berkeley, is president.

COLORADO

Society News—At a meeting of the Northeast Colorado Medical Society in Sterling, October 14, Dr. Alfred R. Masten, Denver, spoke on 'Tuberculosis and the Family Physician'.—The Mesa County Medical Society was addressed October 19, among others, by Dr. Galen M. Hoyer, Grand Junction, on 'Functional Disorders of the Digestive Tract'.—Dr. Paul S. Wolfe, Pueblo, discussed fever therapy before the Pueblo County Medical Society, October 19.

CONNECTICUT

Monthly Lectures in Different Towns—The Fairfield County Medical Association has built its program for the coming year around a discussion of the heart and related subjects, in cooperation with local medical societies throughout the county. Dr. Milton C. Wintermütz, Anthony N. Brady, professor of pathology, Yale University School of Medicine, New Haven, opened the series in Springdale October 6 with 'Pathology of Arteriosclerosis' as his subject. The monthly meetings will be held in a different town each time and other speakers all of New Haven, will include:

Dr. Louis H. Nahum: Coronary Diseases—Diagnosis and Therapy.
Dr. John R. Paul: Rheumatic Cardiovascular Conditions.
Dr. George Blumer: Subacute Bacterial Endocarditis.
Dr. Harold M. Marvin: Myocardial Failure.
Dr. Clarence L. Robbins: Edema: Its Differentiation and Treatment.
Dr. Harry M. Zimmerman: Vascular Diseases of the Central Nervous System.
Dr. Ashley W. Oughterson: Peripheral Vascular Disease—Its Conservative Treatment.

DISTRICT OF COLUMBIA

Annual Tuberculosis Meeting—The annual public meeting and 'health crusade' of the District of Columbia Tuberculosis Association will be held in the auditorium of the U. S. Public Health Service November 22. A symposium on 'How to Protect Your Home Against Tuberculosis' will be presented with the following speakers:

Dr. Jay Arthur Myers: Minneapolis: Modern Methods in the Control of Tuberculosis.
Dr. Cameron St. C. Guild: New York: The High Incidence of Tuberculosis Among Negroes.
Dr. James G. Townsend: Washington: Milestones Toward Adequate Hospitalization for the Tuberculous in the District of Columbia.

ILLINOIS

Report on Alcoholism—Damage to health from alcoholism is apparently increasing in Illinois, particularly among women, according to a state health department report. During the last five years, a sharp upward trend has marked the death rate from cirrhosis of the liver. Although the number of deaths attributed directly to alcoholism (123) was the same in 1932 and in 1936, the number attributed to cirrhosis of the liver went up from 743 to 907, a rise of 22 per cent. The increase in mortality from cirrhosis of the liver during the last five years was equal to the increase during the preceding decade in Illinois, indicating that some factor has been introduced or increased in magnitude to accelerate the upward trend. Among women the mortality attributed directly to alcoholism in 1936 was more than double what it was in 1932, four and nine in the two years, respectively.

Chicago

Hospital News—"Twenty Years at the Carville Louisiana Leprosarium" was described by Sister Catherine at a meeting at St. Joseph Hospital, November 10. The paper was discussed by Rev. Father M. J. O'Connell, president of DePaul University, and Dr. Morris Fishbein, Editor of THE JOURNAL.

Louis A. Greensfelder Memorial Lectureship—Dr. Corneille Heymans, professor of pharmacology and therapeutics, University of Ghent, Belgium, will present the Louis A. Greensfelder Memorial Lecture at the Rothschild Auditorium, Michael Reese Hospital, November 23, on "The Physiological Considerations of Surgical Intervention in Hypertension." Discussions will be presented by Drs. Harry Goldblatt, professor of experimental pathology, Western Reserve University School of Medicine, Cleveland, on "Surgical Application of the Physiological Principles in Experimental Hypertension." Max M. Peet, professor of surgery, University of Michigan Medical School, Ann Arbor, and Alfred W. Adson, professor of neurosurgery, University of Minnesota Graduate School of Medicine, Rochester, Minn., "Surgical Application of Physiological Principles in Clinical Hypertension."

Society News—Marion Hood, Ph.D., discussed "Trichinosis" and Bertha Kaplan Spector, Ph.D., "Amoebiasis" before the Chicago Council of Medical Women November 5.—At a meeting of the Chicago Surgical Society, November 5, Dr. John Martin discussed "Ventricular Changes in the Presence of Intracranial Pathology, with Demonstration of Models."—The Chicago Pathological Society was addressed November 8, among others, by Drs. Paul R. Cannon and Theodore E. Walsh on "Potential Dangers of Intranasal Medication."—At a meeting of the German Medical Society of Chicago, November 2, Drs. Leo J. Latz and Franklin E. Hall discussed "Recent Studies on Fertility and Sterility in Women" and "The Inverted Uterus" respectively.—Dr. Maurice I. Kaplan, among others, addressed the Chicago Society of X-Ray Technicians November 4 on "Anatomy and Physiology of the Gastro-Intestinal Tract."—The Chicago Gynecological Society was addressed November 19 by Drs. Max Cutler on "Complications Associated with the Radiation Treatment of Cancer of the Cervix" and Edward L. Cornell and Dorris F. Rudnick on "Clinical Manifestation and Treatment of Stricture in Women."

Campaign Against Quacks—The Illinois State Department of Registration and Education, Springfield, has been conducting a campaign against illegal practitioners. Following is a list of those cases which have come to trial:

Helena Modzelewski, 2718 West Twenty Third Street, found guilty October 28 and fined \$100 and costs.

Joseph Costello, 2801 West Harrison Street, pleaded guilty September 20, sentenced to ten days in county jail and placed on six months probation.

August Dietz, 6141 Dorchester Avenue, pleaded guilty September 9 and placed on one year's probation.

E. A. Romanoski, 1240 North Damen Avenue, pleaded not guilty, found guilty September 28, fined \$100 and costs and sentenced to ten days in the county jail.

Sidney Butler, 4554 Broadway, pleaded guilty November 2 and fined \$100 and costs.

L. A. Cline, 2025 South Western Avenue, found guilty and placed on six months probation.

Elmer L. Spencer, 13008 South Western Avenue, Blue Island, sentenced October 16 to thirty days in jail and fined \$150 and costs; defendant will appeal.

Harry Trestrail, 3325 North Lincoln Avenue, pleaded guilty September 27 and fined \$100 and costs.

Niketas D. Vliarinos, 1714 West Madison Street, fined \$100 and costs October 11 and sentenced to twenty days in jail. Unable to pay fine will have to serve fine in jail at \$1.50 per day.

Anna Zbieranek, 9139 Commercial Avenue, found guilty October 26 and fined \$100 and costs.

A. A. Williams, Aurora, Ill., pleaded guilty October 5, fined \$100 and cost.

INDIANA

Society News—The Indianapolis Medical Society was addressed November 9 by Drs. Albert Murray DeArmond and Frederic W. Taylor on "The Midbrain and Its Role in the Production of Clinical Symptoms" and "Gunshot Wounds of the Abdomen" respectively. Dr. Claude S. Beck, Cleveland, will give an address on "Recent Developments in the Surgery of the Heart" before the society November 20. Dr. Eugene B. Mumford will present a paper entitled "Treatment of Fractures of the Hip" before the society November 30, and Dr. Arthur F. Weyerbacher, Tumors of the Testicle.—Dr. Robert M. Moore, Indianapolis, discussed "Cardiovascular Emergencies" before the Jasper-Newton County Medical Society in Remington October 28.—At a meeting of the Fort Wayne Medical Society in Fort Wayne November 2, Dr. Paul A. O'Leary, Rochester, Minn., spoke on "The Treatment of Syphilis."—The Fountain-Warren County Medical Society was addressed in Kramer, November 4, by Dr. Frank W. Peyton, Lafayette, on "The Management of Abortions."—At a meeting of the St. Joseph County Medical Society in South Bend, October 26, Dr. Carl J. Rudolph, South Bend, discussed "Efficiency of the Eyes."—The Gibson County Medical Society was addressed in Princeton, October 11, by Dr. John M. Cunningham, Indianapolis, on "Diagnosis and Treatment of Chronic Appendicitis."—At a meeting of the Elkhart County Medical Association in Elkhart, October 13, Dr. Philip H. Kreuscher, Chicago, spoke on brachial plexus.—At a meeting of the Tipton County Medical Society, Tipton, October 15, Dr. John R. Brayton, Indianapolis, discussed "Skin Diseases of Childhood and Early Adult Life."

KENTUCKY

Psychiatric Association Formed—The Kentucky Psychiatric Association was recently organized at a meeting in Lexington with the following officers: Drs. Isham Kimbrell, Lexington, president, S. Spafford Ackerly, Louisville, vice president, and Robert H. Felix, Lexington, secretary. The first meeting will be held in Louisville January 8. The stated objectives of the society are "to further the study of subjects pertaining to the nature, treatment and prevention of nervous and mental disorders, to further the interests, the maintenance and advancement of standards of hospitals for nervous and mental disorders or outpatient clinics, and of all other agencies concerned with the medical, social and legal aspects of these disorders, to further psychiatric education and research and to apply psychiatric knowledge to other branches of medicine to other sciences and to the public welfare of the citizens of the state of Kentucky."

MASSACHUSETTS

Personal—Albert Baird Hastings, Ph.D., Hamilton Kuhn, professor of biochemistry, Harvard University Medical School, has been appointed a member of the Medical Fellowship Board of the National Research Council for the period ended June 30, 1941, to complete the unexpired term of Dr. Walter B. Cannon, Cambridge, resigned.

Society News—Dr. Roger I. Lee, Boston, read a paper entitled "Coronary Thrombosis: A Clinical Entity That Differs in Practice from Textbook Description" before the Hampden District Medical Society, October 26.—The Massachusetts Society for Mental Hygiene was addressed at its annual meeting in Boston, November 17, by Lincoln D. Lynch, superintendent of schools, Norwood, on "A Child Guidance Department for Elementary Schools." The Norwood School Project and Donald D. Durrell, Ed.D., professor of education and director of the educational clinic, school of education, Boston University, on "Educational Adjustments to Individual Needs."

Sunday Afternoon Lectures—Free public health lectures are being given on Sunday afternoons under the auspices of Beth Israel Hospital, Boston, and the woman's auxiliary. The first lecture was delivered November 7 by Dr. Charles F. Wilensky on "The Prevention and Control of Disease." The remaining lectures in the series include:

Dr. Elliott P. Joslin, November 21, Diabetes: Its Cause and Treatment.

Dr. Harry Linenthal, December 5, You and Your Doctor.

Dr. Charles G. Mixter, December 19, Appendicitis and Other Abdominal Emergencies.

Dr. Herman L. Blumgart, January 9, High Blood Pressure and Heart Disease.

Dr. Harry F. Friedman, January 23, What to Do About Cancer.

Dr. Harry C. Solomon, February 6, Mental Health.

Dr. Jacob H. Swartz, February 20, Dangers That Lurk in Cosmetics.

Dr. Armin Klein, March 6, What Can Be Done in Arthritis.

MICHIGAN

Dedication of Deaconess Hospital—The dedicatory program of the new building of the Evangelical Deaconess Hospital, Detroit, took the form of a clinic November 10. A clinical pathologic conference by Dr Plinn F Morse opened the program with Dr Raymond B Allen, dean of Wayne University College of Medicine, acting as chairman. Guest speakers included

Dr Irving W Potter Buffalo
Dr Wilms D Gatch dean and professor of surgery Indiana University School of Medicine Indianapolis
Dr Albert C Furstenberg dean and professor of otolaryngology University of Michigan Medical School Ann Arbor
Dr Elliott P Joslin clinical professor of medicine Harvard University Medical School Boston

MONTANA

Graduate Courses—The Medical Association of Montana sponsored a series of graduate meetings in Billings November 8-9, Anaconda November 10-11 and Havre November 12-13, with the Hill County, Yellowstone Valley and Mount Powell medical associations cooperating. The program included the following speakers

Dr Karl W Laymon instructor in syphilis and dermatology University of Minnesota Medical School Minneapolis
Dr Myne G Peterman professor and director of the department of pediatrics Marquette University School of Medicine Milwaukee
Dr Morris Edward Davis associate professor of obstetrics and gynecology, Division of Biological Sciences University of Chicago

Dr Laymon gave a public lecture in Billings on syphilis, November 8. Dr Peterman in Anaconda, November 10, "What Your Physician Will Do for You," and Dr Davis in Havre, November 12, "Modern Motherhood."

NEBRASKA

Hospital News—Bryan Memorial Hospital Lincoln, presented a "Clinic Day" October 1 with the following members of the faculty of the University of Minnesota Medical School Minneapolis in charge of the program: Drs Cecil J Watson, William T Peyton, Charles D Creevy and James S McCartney.

District Meetings—A program on diabetes was presented at a meeting of the Seventh Council District Medical Society in Davenport October 14 by Drs Frank M Conlin, Frank Lowell Dunn and Morris Margolin, all of Omaha, and Floyd L Rogers, Lincoln. A joint meeting of the Ninth and Tenth Council District Medical Societies was held in Holdrege September 30, with the following scientific program: Drs Donaldson W Kingslev, Hastings, on "Carcinoma of the Prostate," Philip H Bartholomew, Lincoln, "State Health Program" and George Alexander Young, Omaha, "Infantile Paralysis." Dr Homer Davis, Genoa, president-elect of the Nebraska State Medical Association, spoke on medical organization. The Twelfth Council District Medical Society held a joint meeting with the Western Nebraska District Dental Society in Alliance, September 30. Omaha speakers presented the scientific program as follows: Drs William L Shearer, "Focal Infections of Dental Origin," Herman F Johnson, "Indications for Open Reduction of Fractures and Dislocations," and Rollin Russell Best, "Lesions of the Rectum and Colon."

NEW YORK

Changes at Albany Medical College—Dr Victor C Jacobsen, Troy, has been appointed associate professor of medicine at Albany Medical College, Albany, and attending physician to the Albany Hospital. Dr Jacobsen was professor of pathology at the college from 1921 to 1934. Dr Lloyd H Ziegler, professor of neurology and psychiatry, has resigned to become associate medical director of the Milwaukee Sanitarium, Milwaukee, and lecturer in psychiatry at the University of Illinois College of Medicine, Chicago.

Stop Distribution of Polyvalent Serum—The division of laboratories and research of the New York State Department of Health announces that it has discontinued distribution of typhoid-paratyphoid vaccine and of polyvalent antidyenteric serum. This action was taken after it was found that the incidence of paratyphoid was extremely low in the state and that vaccines containing paratyphoid B strains were likely to cause more severe reactions in certain persons than the typhoid antigen. With respect to the polyvalent antidyenteric serum, it was stated that the distribution has been extremely limited in recent years and that the serum appears to be effective mainly against the more toxic Shiga strains, which are rare in the state.

Meeting on Cancer in Buffalo—A group of talks on the cancer problem was presented at a meeting in Buffalo October 28 as the second of a series of health talks under the auspices of the Buffalo Academy of Medicine, the Medical Society of the County of Erie, the Eighth District Dental Society, the American Society for the Control of Cancer and the Health Division of the Council of Social Agencies. The speakers were Clarence C Little, Sc D, Bar Harbor, Maine, "The Campaign Against Cancer," Drs Burton T Simpson Buffalo, "Scientific Facts About Cancer for Doctor and Layman," John M Swan, Rochester, "What the Layman Should Know," and Karl F Eschelmann, Buffalo, "Diagnosis and Treatment for Cancer in a Public General Hospital."

Society News—Dr Descum C McKenney, Buffalo, addressed the Medical Society of Niagara County, Lockport, October 12, on "Rectal Emergencies in General Practice." Dr Harold D Harvey, New York, addressed the Otsego County Medical Society recently in Cooperstown on "Early Efforts to Evaluate the Results of Sulfanilamide." Drs Ferdinand J Schoeneck, Syracuse, and Ross E Herold, Willard, addressed a meeting of the Seneca County Medical Society at the Willard State Hospital, October 14, on "Disproportion in Obstetrics" and "Insulin Shock Treatment in Dementia Praecox" respectively. Dr John Worden Kane, Binghamton, addressed the Broome County Medical Society, Binghamton, November 9, on "Neurosurgical Problems." Dr Robert A Kilduffe, Atlantic City, N J, addressed the Binghamton Academy of Medicine, October 19, on "Clinical Utilization of Blood Studies."

New York City

The Brickner Lecture—Dr Sterling Bunnell, San Francisco, gave the seventh Walter M Brickner Lecture at the Hospital for Joint Diseases, November 18, on "Reconstructive Surgery of the Injured Hand."

Hospital News—An oil painting of Dr Adolph Bonner and a bronze plaque of Dr John Linder were presented to the Jewish Hospital of Brooklyn at a ceremony November 4 in recognition of their services as members of the medical staff. Dr Bonner graduated from the College of Physicians and Surgeons of Chicago in 1896, and Dr Linder graduated from the University and Bellevue Hospital Medical College in 1904.

Annual Hospital Fund Campaign—The United Hospital Fund, representing ninety-two voluntary hospitals, opened its annual campaign for funds with a dinner at the Hotel Commodore, October 25. John W Davis is chairman of the campaign. No definite goal was set, but it was announced that the minimum needs of the member organizations aggregate \$3,171,134. It was reported November 15 that \$833,003 had been pledged.

Personal—Dr Alexis Carrel of the Rockefeller Institute for Medical Research received the honorary degree of doctor of science from the Board of Regents of the University of the State of New York at its seventy-third convocation, October 15. Dr Haven Emerson, professor of public health practice, College of Physicians and Surgeons, Columbia University, received an honorary doctor's degree at the recent celebration of the hundredth anniversary of the University of Athens.

Program of Heart Disease Lectures—Dr Irving R Roth delivered the first of a series of lectures on heart disease, sponsored by the New York Heart Association, November 9, on "Management of Patients with Heart Disease." Lectures for the remainder of the year are as follows:

Dr Sidney P Schwartz Use of X Rays and Fluoroscopy in the Management of Heart Diseases November 23
Dr Arthur M Master Use of Electrocardiograms in the Diagnosis and Prognosis of Coronary Thrombosis December 14
Dr Harry Gold Diagnosis and Treatment of Disorders of Rhythm Clinical and Electrocardiographic Aids December 28

Illegal Practitioners Convicted—The New York State Board of Medical Examiners has recently reported conviction and sentence of the following illegal practitioners:

Abram S Rosenstein three months in the workhouse sentence suspended during good behavior
Jack K Siegal thirty days in the workhouse and a fine of \$500 in default of which he was to serve another thirty days
Louis Raskin a fine of \$200 in default of which he was to serve thirty days in the workhouse
Stanley Mack a fine of \$200 in default of which he was to serve thirty days in the workhouse
Vincent J Morrow a fine of \$100 in default of which he was to serve thirty days in the workhouse
Carl Talbot (alias Roger Jabo alias Roger Rabo) sentenced to pay a fine of \$100 in default of which he was to serve sixty days in the city prison

OHIO

The Rachford Lectures—Albert Baird Hastings, Ph.D., Hamilton Kuhn professor of biological chemistry, Harvard University Medical School, Boston, delivered the seventh annual series of Benjamin Knox Rachford Lectures at the University of Cincinnati College of Medicine, November 11-12. Dr. Hastings' subjects were "The Distribution of Salts and Water in the Body" and "Experimental Observations on Dehydration and Edema."

University News—A tablet was dedicated at Western Reserve University School of Medicine October 29 to the memory of John Lund Woods, first extensive donor to the school. In 1881 Mr. Woods contributed to the purchase of the Cleveland campus, in 1886 he gave \$175,000 for a new building for the school of medicine and in 1892 an endowment of \$125,000, said to have been one of the first large gifts to medicine. He died in 1893. Drs. John Pascal Sawyer, professor emeritus of therapeutics and clinical medicine, and Torald H. Sollmann, dean of the medical school, were the speakers at the ceremony.

OREGON

Annual Registration Due December 1—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to register annually on or before December 1, with the secretary of the board of medical examiners, and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days or part thereof of default, and his failure to reregister within ninety days after December 1 is a misdemeanor.

PENNSYLVANIA

Society News—Drs. Isidor S. Ravdin and Edward L. Bortz, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, November 12, on "Nutritional Problems in Surgical Patients" and "Modern Treatment of Pneumonia" respectively. Dr. Louis H. Clerf, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, November 9, on "Diagnosis and Treatment of Suppurative Diseases of the Lung."

Cancer Symposium—The Lehigh and Northampton county medical societies arranged a symposium on cancer for physicians and the public in Allentown November 18. During the day a scientific program was presented with the following speakers: Drs. William F. Rienhoff Jr. and Hugh H. Young, Baltimore; Vernon C. David, Chicago; George P. Muller, Leon Herman, Thomas A. Shallow and P. Brooke Bland, Philadelphia; and William L. Estes Sr., Bethlehem. In the evening Dr. Wilmer Krusen, Philadelphia, gave a public address at the Allentown High School on "What Everybody Should Know About Cancer."

Hospital Graduate Seminar—Easton Hospital, Easton, presented its eighth annual graduate seminar October 20 with the following instructors: Drs. Edward H. Dennen, New York, on "Choice of Instrument in Delivery with Forceps"; Theodor Blum, New York, "Medicolegal Cooperation in General and Special Practice"; Raphael Kurzrok, New York, "The Menopause"; George P. Muller, Philadelphia, "Stone in the Common Duct"; and John F. Mahoney, U. S. Public Health Service, Washington, D. C., "The Public Health Service Plan for the Control of Venereal Diseases."

Philadelphia

University News—Memorial rooms for Dr. Henry R. M. Landis, for many years director of the clinical and sociological departments of the Henry Phipps Institute, University of Pennsylvania, have been established in the suite he occupied at the institute. Dr. Landis died September 14.

Alvarenga Prize for 1938—The College of Physicians of Philadelphia announces that the Alvarenga Prize for 1938 amounting to about \$200, will be awarded July 14, 1938 to the author of the best work on any branch of medicine which may be deemed worthy of the prize. The prize paper will be selected from contributions published since January 1 and brought to the attention of the committee before May 1, 1938, by the author or by other sponsors, or from unpublished studies submitted to the committee in typewritten manuscript and received before May 1. Communications should be addressed to the Alvarenga Prize Committee, 19 South Twenty-Second Street, Philadelphia.

RHODE ISLAND

Society News—Drs. Ernest M. Daland and Richard H. Miller, Boston, addressed the Providence Medical Association November 1, on "Treated versus Untreated Cancer" and "Ulcer and Cancer of the Stomach and Ulcer of the Duodenum" respectively. Dr. Charles Bradley, East Providence, among others addressed the October meeting on "The General Practitioner and the Feebleminded Child."—Dr. Jesse P. Eddy III, Providence, addressed the Washington County Medical Society, Westerly, October 13, on "Blood Transfusions."

SOUTH CAROLINA

District Meetings—At the semiannual meeting of the First District Medical Association in Walterboro, November 18, a symposium on gastro-intestinal diseases was presented by Drs. William M. Bennett, Ruffin, George C. Brown, Walterboro, Joseph N. Walsh, Moncks Corner, and William H. Kelley, Charleston. Dr. Frederick E. Kredel, Charleston spoke on injuries to the head.—Dr. Edgar G. Ballenger, Atlanta, Ga., was the guest speaker at a meeting of the Fourth District Medical Society in Seneca, October 26. Other speakers included Drs. John M. Fleming, Spartanburg, on "Toxemias of Pregnancy"; Kent H. Smith, Greenville, "Congenital Urological Difficulties in Children"; James R. Young, Anderson, "Management of Acute Osteomyelitis"; and John F. Ramey, Greenville, "Management of Congestive Heart Failure."

TENNESSEE

Faculty Changes at Vanderbilt—Dr. Samuel L. Clark, associate professor of anatomy at Vanderbilt University School of Medicine, Nashville, has been promoted to a full professorship of anatomy, newspapers reported October 31. Dr. Alfred Blalock, associate professor of surgery, has also been made professor, and Dr. William DeGutierrez Mahoney, formerly of New Haven, Conn., now studying in London, has been appointed assistant professor of neurology, effective July 1, 1938. Dr. Frank H. Luton was promoted from assistant to associate professor of psychiatry and Dr. Charles M. Hamilton from instructor to assistant professor of clinical dermatology.

WASHINGTON

Personal—Dr. William E. Steele, Olympia, has resigned as chief medical adviser for the state department of labor and industries to enter private practice in Longview.

Society News—Dr. Frederick Lemere, Seattle, addressed the Grays Harbor County Medical Society, Aberdeen, September 15, on "Insulin Shock Treatment of the Psychoses."—Drs. Donald V. Trueblood, Seattle, and Edwin J. Barnett, Spokane, addressed the Spokane County Medical Society, Spokane, October 14, on "Tumors of the Neck and Parotid Gland" and "Wood Tick Paralysis in a Child" respectively. Dr. William W. Bauer, director of the Bureau of Health and Public Instruction, American Medical Association, Chicago, spoke at a special meeting October 26 on "The Place of the Doctor in the Community Health Program."

WEST VIRGINIA

Society News—Dr. Richard O. Rogers, Bluefield, was elected president of the Hospital Association of West Virginia at its recent annual session in Wheeling. Dr. William S. Fulton, Wheeling, president of the West Virginia State Medical Association, spoke at the annual banquet on cooperation between hospitals and the medical profession.—Dr. Raymond A. Ramsey, Columbus, Ohio, addressed the Cabell County Medical Society, Huntington, October 14, on "The Diagnostic Criteria of Hyperthyroidism and Hypothyroidism."—A symposium on peptic ulcer was presented before the Kanawha Medical Society, Charleston, October 14, by Drs. Alfred Sprites Brady Jr., Hugh A. Bailey, and Vernon L. Peterson, all of Charleston.—Dr. Jerome E. Andes, Morgantown, addressed the Monongalia County Medical Society, October 5, on "Diagnosis and Treatment of Uterine Bleeding."—Dr. Allen A. Tombaugh, McConnellsville, Ohio, addressed the Parkersburg Academy of Medicine, October 7, on "Early Diagnosis of Pulmonary Tuberculosis."—At a meeting of the Raleigh County Medical Society at Beckley recently Dr. Russel Kessel, Charleston, spoke on pelvic infections.—Dr. William F. Bransch, Rochester, Minn., addressed the Ohio County Medical Society, Wheeling, November 4, on "Common Lesions Found in the Urinary Tract of Children."

GENERAL

Hoeber Firm Will Continue—The firm of Paul B Hoeber Inc, which is the medical book department of Harper & Brothers, New York, will continue with Mr Paul B Hoeber Jr as his father's successor, according to a recent announcement. The *Annals of Medical History* will be continued under the general editorship of Dr Francis R Packard, Philadelphia. Mr Hoeber died August 20.

Changes in Status of Licensure—The Colorado State Board of Medical Examiners has reported the following action:

Dr Lewis J Greenfield, Denver, license restored October 5.

The Georgia State Board of Medical Examiners revoked the following licenses at a recent meeting for violation of the Harrison Narcotic Act:

Dr J W Lundy, Macon
Dr Z McD Story, Thomson

Results of Special Examinations—Seventy-nine out of 101 candidates were certified after an examination by the American Board of Otolaryngology in Chicago, October 8-9. An examination will be held in San Francisco June 10-11, 1938, prior to the annual session of the American Medical Association. Prospective applicants for certificates should obtain application blanks from the secretary, Dr William P Wherry, 1500 Medical Arts Building, Omaha, Neb.

Air Hygiene Meeting—The fall meeting of the Air Hygiene Foundation of America will be held November 30 at Mellon Institute, Pittsburgh. Reports will be presented by the medical, legal and preventive engineering committees, covering these three aspects of the occupational disease problem. Among the speakers will be Philip Drinker, Ch E, Boston, Dr Leroy U Gardner, Saranac Lake, N Y, Dr Anthony J Lanza, New York, and Dr Eugene P Pendergrass, Philadelphia.

Atlas of Dermatology—The ninth International Congress of Dermatology will publish in February 1938 an atlas of dermatology with 1,100 pages containing more than 4,000 illustrations (many in color) contributed by physicians of forty-four countries. Comparatively few copies will be sold and there will be no second edition, according to an announcement. Those who are interested in the atlas are requested to write without delay for a free illustrated prospectus from the Publishing Committee, Ninth International Dermatological Congress, VIII Maria-utca 41, Budapest, Hungary.

Attendants at Negro Births—The U S Bureau of the Census recently released a study of Negro births in the United States and the persons in attendance at these births. There were 255,125 births, of which 85,732, or 33.6 per cent, were in cities and 169,393, or 66.4 per cent, in the rural areas. Mississippi had the largest number of births, 26,259, and Idaho had none. Of the total number 44,059, or about 17 per cent, were attended by physicians in hospitals, 66,218, or about 26 per cent, by physicians not in hospitals, 142,791, or 56 per cent, by midwives, and 2,057, or nearly 1 per cent, by relatives, friends and neighbors. More than 10,000 births were attended by midwives in Mississippi, Georgia, Alabama, South Carolina, North Carolina and Louisiana. Texas, Massachusetts, Virginia and Arkansas reported the greatest number of Negro births unattended by physicians or midwives. The rates of Negro deaths under 1 year per thousand live births in states where midwives attended the largest number of births were reported as follows: Alabama, 80.8, Arkansas, 48.6, Delaware, 134.1, Florida, 88.3, Georgia, 80.6, Louisiana, 85.3, Mississippi, 59, North Carolina, 89.8, South Carolina, 95.8, Texas, 83.1, and Virginia, 96.2. The white infant mortality rates in these states ranged from 46.7 in Arkansas to 70.2 in Texas.

Southern Medical Association—The thirty-first annual meeting of the Southern Medical Association will be held in New Orleans November 30-December 3, at the Municipal Auditorium. Tuesday will be New Orleans Day, with general clinical sessions held separately for medicine, surgery, gynecology and obstetrics, ophthalmology and otolaryngology. All the speakers will be New Orleans physicians. Tuesday evening there will be a general public session with the following speakers:

Dr Stewart R Roberts, Atlanta, Ga, Your Health and Mine
Dr John Shelton Horsley, Richmond, Va, The Menace of Cancer
Dr Arthur T McCormack, Louisville, Ky, The Romance of Immunization

Rev Alphonse M Schwitala, St Louis, Society's Debts to the Doctor

Wednesday morning there will be two general sessions representing all specialties. At these meetings the speakers will include:

Dr Irvin Abell, Louisville, Ky, President Elect of the American Medical Association
Acute Abdominal Emergencies

Dr Frank H Lahey, Boston, Modern Developments in Anesthesia and Anesthetics
Dr James R Bloss, Huntington, W Va, Home Obstetrics
Dr Marvin A Stevens, New Haven, Conn, Sport Injuries
Dr Frank C Mann, Rochester, Minn, Physiologic and Pathologic Reactions of the Liver

Speakers listed on the program to address section meetings include:

Dr Robert A Cooke, New York, Medical Problems of the Allergist
Dr Priscilla White, Boston, Protamine Insulin in the Treatment of Juvenile Diabetes
Eleanor A Bliss, Sc D, Baltimore, The Differentiation of Hemolytic Streptococci and Its Relation to Sulfanilamide Therapy
Dr Perrin H Long, Baltimore, Further Observations upon the Use of Sulfanilamide and Its Derivatives
Dr Walter C Alvarez, Rochester, Minn, Some Stages in the Development of Gastroenterology
Dr George S Stevenson, New York, History of the Mental Hygiene Movement in America
Dr Lawrence Reynolds, Detroit, Pulmonary Cysts
Dr Raymond A Vonderlehr, Washington, D C, Control of Syphilis in the Southern States
Dr Arthur W Allen, Boston, The Role of Surgery in Peptic Ulcer
Dr Henry H Kessler, Newark, N J, Cineplastic Operations
Dr Jean Paul Pratt, Detroit, Treatment of the Menopause
Dr Frederick H Falls, Chicago, The Use of Progestin in Obstetric Complications
Dr Thomas J Kirwin, New York, The Problem of Bladder Tumors and Their Treatment
Dr Gabriel Tucker, Philadelphia, Benign Tumors of the Larynx: Diagnosis and Treatment
Dr William L Benedict, Rochester, Minn, Concerning Exophthalmos with Special Reference to Goiter
Dr William D Cutter, secretary, Council on Medical Education, American Medical Association, Chicago, The Appraisal of Medical Schools
Dr Carlos E Finlay, Havana, Cuba, Medical Education in Cuba: Recent Reforms and Future Plans

The following organizations will hold their annual meetings in conjunction with the association: the American Society of Tropical Medicine, the southern branch of the American Public Health Association, the National Malaria Committee, Region II of the American Academy of Pediatrics, the southern section of the Society for Experimental Biology and Medicine and a special round table group of allergists.

FOREIGN

Nobel Prize Awarded to Professor Szent-Gyorgyi—The 1937 Nobel Prize for Physiology and Medicine has been awarded to Prof Albert Szent-Gyorgyi, professor of medical chemistry, Szeged University, Szeged, Hungary, "as a reward for his discoveries on the biological process of combustion, especially in relation to vitamins A and C." Professor Szent-Gyorgyi has carried on his research in laboratories in Austria, Germany, England and the United States. He spent some time at the Mayo Clinic, Rochester, Minn, and in Chicago and has lectured at Harvard University. His main achievement has been the isolation and chemical analysis of vitamin C, which he produced in pure form from peppers.

Plans for Congress of Physiology—The sixteenth International Physiological Congress will be held in Zurich, Switzerland, Aug 14-18, 1938, under the presidency of Prof W R Hess of the University of Zurich. The general secretary is E Rothlin, Basle. All members of physiologic, biochemical, experimental pathologic and pharmacologic institutes or laboratories are entitled to participate, those who are not members of any recognized laboratory or institute must be recommended by the director of a recognized laboratory or institute or by the president of a recognized society. The congress will meet in six sections as follows: general and comparative pathology, physiology, biophysics, biochemistry, applied physiology, psychophysiology and pharmacology. Before the congress there will be an international meeting for cell research, August 7-13, under the presidency of Prof von Moellendorff of the Anatomical Institute, Zurich.

Deaths in Other Countries

Hans Christian Jacobaeus, professor of medicine, Stockholm Medical Institute, died October 29, aged 58. He is known for a method of cauterizing pleural adhesions.

CORRECTION

Rhoads Instead of Rhodes—Dr W B Castle, Boston, has called attention to the misspelling of an author's name mentioned in the Current Comment entitled 'Experimental Anemia,' page 1458, THE JOURNAL, October 30. In the several times that this author's name was used, it should have been spelled Rhoads instead of Rhodes.

Treatment of the Undescended Testicle

The pathology and treatment of the undescended testicle are still controversial subjects. It has not been settled whether the testicle fails to descend because of imperfect development or is imperfectly developed because it has not descended. In opening a discussion on the treatment at the Royal Society of Medicine, Prof. Grey Turner said that he had never been satisfied that descent occurs later than the age of 3 years, but he suggested that detailed information on this point might be obtained from school medical officers. As shown later, this was forthcoming. He thought that the unilateral and bilateral cases might belong to entirely different groups. In the unilateral the scrotum was always developed, but the testicle which was descended and the penis might be small or abnormally large and rarely were grossly undeveloped. In the bilateral cases there were certainly two groups. In one the external genitals were very small and ill developed, with scarcely the appearance of a scrotum. In the other the penis was fully or even abnormally developed and the scrotum was normal. It was the latter group which was said to beget children. In both groups, secondary sexual characteristics were present though not equally developed. It was unlikely that the underlying problem was the same in the two, for in one there was obviously some general lack of development of the whole genital apparatus whereas in the other this lack appeared to affect only the testicle. In the former some general endocrine stimulus appeared to be the most important requirement, in the latter the mechanical assistance of surgery might supplement or even supplant such treatment.

It had been customary to assume that if a testicle, however small, could be successfully returned to the scrotum, it would develop normally. But this did not always hold. Turner had found that, if after reposition the organ was going to develop, it did so almost at once. If not, probably development would not occur. In a good many cases of successful replacement the condition was probably an ectopic testicle rather than one which had failed to descend.

Although endocrine treatment had given encouraging results, it failed in many cases. If it failed after twelve months' trial in those who had arrived at puberty, operation should be undertaken. Knowledge is desired whether endocrine treatment will make a testicle develop after it has been brought into the scrotum surgically but seems reluctant to mature. He suggested that probably the best time for operation was between the ages of 10 and 14 and that operation was still worth while when the patient presented himself later. Even in adults, if the organ was well developed, replacement had some psychological advantage.

Dr. R. E. Smith, medical officer of Rugby School, said that he had under observation 600 boys between the ages of 13 and 18 in one school and some 400 between the ages of 9 and 18 in another. In six years he had collected data on twenty-three cases of undescended testicle and found that the testicles usually descended into the scrotum at puberty in the majority of those who reached it. The age of descent varied from $12\frac{3}{4}$ to $14\frac{1}{4}$ years in seven cases. In an eighth it was $16\frac{1}{2}$ years, but this boy had general endocrine deficiency. Of three failures one had an ectopic testis and one had had an unsuccessful operation at the age of 8 years. The remainder of the boys being observed have not reached puberty, their ages being from 9 to 14 years. Dr. Smith therefore concluded that the undescended testes should be left to nature until puberty, provided

ectopic testes can be excluded. If no change then occurs, gonadotropic extract should be given in full doses. If this fails, the aid of the surgeon should be sought to ascertain whether some abnormality is preventing descent.

The Prevention of Tuberculosis

In a letter to the *Times*, Sir Pendrill Varrier-Jones, the pioneer of the village settlement for the treatment of tuberculosis, points out that our present system is sadly lacking in prevention. Large numbers of patients are discharged from sanatoriums after treatment and are subsequently readmitted. In many cases discharge and readmission are constantly repeated. In other words, infectious patients are being discharged, often at their own request, to their homes, there to spread infection until dire necessity drives them to seek treatment once more. The dismal round is repeated, each time with less hope, while a fresh crop of new cases is added to the dispensary lists. Sanatoriums are not designed for these recurrent cases, the length of stay tends to decrease as time goes on, and the patient is thus at liberty, for increasing periods, to distribute infection everywhere he goes. This obviously is a wasteful method. We are paying large sums for treatment and simultaneously allowing many of the results of that treatment to be destroyed, while imperiling the patient's family and friends. The individual consumptive has to make a considerable sacrifice. He has to be notified. Once notified he may lose his job and his home as well. In return for this sacrifice he obtains no certainty of cure, no certainty even that his family will be protected from the disease or from distress. Three courses are open to us: 1. To ignore the whole question, thus defeating the national health campaign in one important respect. 2. To imprison infectious consumptives in institutions contrary to their wishes and interests, a course which is not in accordance with democratic principles. 3. To provide an anti-infective environment in which they can live, work and earn, and in which therefore they will voluntarily remain. The last course is what Sir Pendrill has already taken in his village settlement.

Lord Rutherford Is Dead

Lord Rutherford, the great experimental physicist, has died at the age of 66 years. Born in New Zealand, he had a distinguished career at Canterbury College, Christchurch, and then worked at Cambridge under J. J. Thomson, in whose researches on the passage of electricity through gases he gave help, especially with regard to ions, by which this passage is accomplished. Thus began Rutherford's epoch-making researches on radioactivity. In 1919 he was appointed Cavendish professor of physics at Cambridge, succeeding in the great line of Maxwell, Rayleigh and Thomson. His work culminated in two hypotheses which lie at the foundation of modern physics: the transmutation of the elements and the constitution of the atom. He suggested the now familiar comparison of the atom to the solar system in which the proton containing practically the mass, was the sun and the electrons were the planets. Radioactivity was simply a consequence of the bursting of the atom, which also gave rise to new atoms. The radium atom gave rise to helium and to a new gas, which in his first doubts as to its nature he cautiously called the 'emanation'. This in its turn exploded after an average life of three or four days. The consequences of this wonderfully fruitful conception were worked out by himself, his pupils and others. He was a lovable personality, an enthusiast in the cause of science without thought of his own advancement and a colleague always ready to give due credit to others. His philanthropy was shown by the devotion of much of his valuable time to the Academic Assistance Council formed in 1933 to assist the scientists and scholars who were the victims of political persecution. He was one of the founders of the council and became its president. Dr. F. Demuth, chairman of the Not

gemeinschaft deutscher Wissenschaftler im Ausland, pays a special tribute to his work for expelled German scholars and scientists. Rutherford has been buried in Westminster Abbey near the tombs of Newton and other great scientists.

PARIS

(From Our Regular Correspondent)

Oct 23, 1937

The French Surgical Congress

This year's French Surgical Congress was held, as in former years, at the Medical School in Paris during the week beginning October 4. A number of foreign surgeons attended, many of whom took part in the discussions of the papers. Among those who were invited to do this on the subject of the treatment of burns may be mentioned Drs McClure of Detroit, Riehl of Vienna, Wilson of Edinburgh, Seemen of Munich and Donati of Milan. As is customary at all large annual meetings here, one or more subjects are chosen, by vote of the members at the preceding annual session, to be dealt with in the form of an analytic review of the literature and the personal experience of the reporters. These reports in the form of a book are sent to each member about a month before the annual meeting so that ample time is allowed to prepare for a discussion. The reports are prepared by members of the congress appointed by the president of the congress at the time the subjects are selected.

THE TREATMENT OF BURNS

The first report at this year's meeting was on the physiologic pathology and treatment of burns. The first part formed the subject of the report by Prof Pierre Duval of Paris and the second part (treatment) of Dr Mourgue-Molines of Montpellier, France. Only burns involving a minimum of one third of the skin surface and of the second and third degrees during the first four days were included. During this early period, the reactions of the organism are entirely due to the burns because infection as a factor does not enter into play until after the fourth day. These first four days are the critical period, during which general disturbances occur so rapidly and in such severe form that the term "phase of intoxication" can be justly applied to this brief period. The mortality during this phase of acute intoxication or toxemia is high. It is 40 per cent if from 25 to 30 per cent of the entire skin surface is involved and 100 per cent if more than 40 per cent is burned. The clinical picture, the humoral changes, the local (cutaneous) and visceral lesions in the human being when considered in the light of the results of animal experiments lead to the conclusion that this phase of intoxication or toxemia is a general one and is due to the absorption of toxic products formed in the burned area. It is similar up to a certain point to the symptoms and lesions of other toxemias by organic (diphtheria, typhoid) or chemical (pyridic bases) products. The toxemia is autogenous in severe burns, the source being in the burned tissues. This acute autogenous intoxication in the first four days of severe burns resembles greatly three other types of toxemia which we are beginning to understand, such as traumatic shock following severe injuries, and the intoxications accompanying roentgen therapy or curietherapy. Their clinical pictures and humoral reactions closely resemble each other. Observations of the physiologic pathology of recent extensive burns and the other toxemias open up a new field of what might be termed diseases due to autogenous intoxication. In animals it has been found that repeated burns confer a state of sensitization, which in turn confers a certain immunity or resistance toward burns.

Dr Mourgue-Molines said that, in spite of the greatly improved methods at present employed, extensive burns are still accompanied by a high mortality rate. This is especially true of children, in whom the fatal issue is out of all proportion to the extent of the burns. Children below 6 years of age constitute from 40 to 45 per cent of fatal cases. The severity of burns, as was pointed out by Professor Duval, is directly related to a

generalized toxemia, hence the first objective to be attained in the treatment is to combat this toxemia. It is useless, and perhaps does more harm than good, to attempt to apply hurriedly a huge dressing in order to avoid exposure of the burned surface to the air. If such a dressing is used, it should be one that can be easily removed. The burned area is not only a source of pain and exposed to infection but is a laboratory in which toxins are being constantly formed and an effort must be made to limit this to the minimum. The less a severely burned person is disturbed during the period immediately subsequent to the accident, the less harm will be done. One's first duty is to give sedatives to keep the patient warm and give stimulation. The general treatment includes the giving of saline solutions, plenty of fluids to combat dehydration, and transfusions. Infection is the first local complication to combat, and this calls for thorough removal of all necrotic tissue in an aseptic manner. In our present state of knowledge, the most rational and practical method of treatment is that first described by the late E. C. Davidson of Detroit, the underlying principle being to coagulate the dead tissues by the local use of tannic acid. It relieves the pain, prevents absorption of toxic products and helps cicatrization. In extensive burns it is best applied in the form of a solution, a combination of silver nitrate and tannic acid, as suggested by A. G. Bettmann of Portland, Ore. These methods were described in detail. Burns seen late or those due to oily substances which risk being infected should not be given the tannic acid treatment. Every granulating surface remaining after treatment should be covered with grafts of one type or another as soon as possible.

The discussion was opened by Dr Roy D. McClure of Detroit, who made a strong plea for the routine use of the tannic acid treatment of burns because it has resulted in a marked reduction in the mortality rate. There have been cases in which recovery occurred even though 55 per cent of the surface was involved. The formation of a protective crust eases the pain, converts wounds with large serous discharges into dry ones, diminishes the risk of infection and shortens the treatment. In addition to this local treatment, efforts are made to increase the patient's resistance by giving dextrose solution and by transfusions. The technique and results at the Ford Hospital were cited.

Dr Riehl of Vienna spoke of the good results in giving transfusions as recommended by him six years ago. Of 160 cases so treated, recovery occurred in 60 per cent. He also employs the tannic acid treatment but prefers the continuous bath for some cases, a treatment which is not as well known as it deserves to be.

Mr Wilson of Edinburgh used the tannic acid treatment in 200 children, of whom sixty-five had extensive burns. A 20 per cent solution is applied and the burn left exposed to the air or the latter artificially heated. Gentian violet or acriflavine is also used to combat the infection and adrenal extracts against the toxemia.

Seemen of Munich cleans the burned surface with a small metallic brush acting as an electrode. The surface is at the same time coagulated by the heat, a protective coating being formed.

Donati of Milan strongly endorsed the methods which aimed to prevent dehydration and intoxication.

Leriche of Strasbourg found that the tannic acid treatment did not prevent humoral changes. He uses mercurochrome in children and in infected burns, but heliotherapy is especially to be recommended for the latter.

Prollet and Limousin of Clermont-Ferrand have used cod liver oil dressings after the shock and toxemia of the first few days have been overcome.

EMBOLISM OF THE ARTERIES

The second report was on the pathologic physiology and treatment of embolism of the arteries of the extremities. The first of these divisions of the subject was assigned to Dr

J. Fiolle of Marseilles. In the summary he stated that one must consider three periods in the embolism cycle. First, that of the initial attack, with both local and general effects, the latter in the form of shock. Second, the period of changes in the arterial wall and thrombosis. Third, the final period of sequels. Taking these up in the order named, the first effect of an embolism is to give rise to reflex general symptoms, usually described as those of shock. Locally, the most prominent phenomenon is arterial spasm, at the onset, where the embolus is lodged and then distal to this point. This spasm is really a defense reaction but does more harm than good. There appears to be an especially sensitive area in the outer coat of an artery, which puts into motion reflexly the contraction of the vessel wall. As a result of this spasm, the circulation throughout all the divisions and collaterals of the blocked artery comes to a standstill. In favorable cases the process does not progress beyond the spasm stage unless some complication appears. Such an embolism is termed abortive (*man-queue*) if the reaction has been very severe and occult if it has taken place with scarcely any local signs. Spontaneous recovery is more frequently observed in arterial embolism of the upper than in that of the lower extremities, because of the ample anastomoses in the shoulder area. Abortive embolism is, however, not rare in the lower extremities, provided it has not taken place in an artery, such as the popliteal, which seems to favor the "fixation" or lodgment of an embolus. It is not always the size of the latter which determines this. At times the occlusion is the direct result of the lodgment at some bifurcation of a relatively small embolus.

In the second period, one must consider the changes in the arterial wall and the resultant thrombosis, which depend on whether the embolus was a septic one or not. The intima is not the seat of the principal changes, as was formerly taught, but rather the adventitia. On the other hand, the tunica media offers a remarkable resistance to inflammatory changes. The changes in this middle coat are rather of a degenerative than an inflammatory type. The adjacent vein also may be involved by extension from the predominantly inflamed tunica adventitia. The vascular spasm referred to as the principal feature of the first stage does not change, so that little blood is able to pass the point of lodgment of the embolus, where thrombosis is already beginning and extending in a proximal direction, thus blocking the orifices of the collaterals. The influence of stasis distal to the point of occlusion of the artery is such that clot formation is more marked distal to the occlusion than proximal to it.

A tiny embolus can be followed by thrombosis which is out of all proportion to the size of this embolus. Fiolle believed that primary arterial thrombosis is rare and that most often a minute embolus has been the starting point. He did not wish to give the impression that the first shock or arterial spasm period was sharply demarcated from the second or vessel changes period. The latter may appear very early and hardly be distinguishable so far as time is concerned from the spasm period.

Abortive embolisms afford an opportunity to study organization as it occurs in spontaneously cured cases. The obliterating clot becomes so firmly organized that at times it is difficult to dislodge. Recovery does take place at times, often accompanied by severe pain as the result of irritation of the sympathetic nerve fibers in the outer coat of the artery, but such abortive cases may run a painless course. As complications, one must keep in mind embolism of various viscera secondary to the same process in the extremities. Another complication is aneurysm formation.

TREATMENT OF EMBOLISM

The treatment of arterial embolism formed the subject of the portion of the report assigned to Dr. Funck-Brentano of Paris. He said that in the present state of our knowledge of the

question the following factors must be taken into consideration:

1. Peripheral ischemia must be regarded as a complication from the anatomic, physiologic and clinical points of view. Whatever treatment is given aims to influence only the effect and not the cause, hence the failures are all due to the particular method employed. A study of the results of operations for arterial embolism can for this reason lead to wrong conclusions.
2. The relative frequency of abortive embolisms ought to make any one very circumspect who studies the question of results. The apparent beneficial influence of any particular operation must always raise the question as to whether the operation was really responsible.
3. The crucial point of the entire question rests in the thrombogenic role of the embolus. The operation embolectomy, as proposed by Einar Key and other Swedish surgeons, aims to remove the obstacle (embolus) and the point of potential expansion of a clot in a distal direction. The anatomic factor dominates in this type of operation. This is why its advocates, knowing that the embolus and the secondary thrombosis present the same dangers, insist on operating within ten hours after the embolism has taken place.

Arterectomy, as proposed by Leriche and a few others, is based on two elements: (a) Anatomic. It suppresses the thrombus-producing area. (b) Physiologic. It allows a collateral circulation to be established. Operations of the indirect type, such as those on the paravertebral sympathetic ganglions only, aim to relieve vascular spasm and ignore the importance of the thrombus-producing properties of the embolus itself. Embolectomy, when carried out early enough and under favorable conditions, has given better results than any other direct operative method. Arterectomy with or without preceding endovascular exploration has a number of indications which are not opposed to embolectomy. Operations on the paravertebral sympathetic ganglions or other types of indirect treatment should be employed only as adjuvants and not as the sole methods of treatment. 4. From a practical standpoint, the indications for treatment depend on the time when the patient is first seen. Within the first ten hours embolectomy is the method of choice, following localization, by means of the clinical and radiographic data, of the level at which the embolism has taken place. The operation should be done with the patient under local anesthesia. If the patient is seen for the first time after an interval of more than ten hours, arterectomy is indicated. This is especially true of cases of long-standing obstruction.

Regardless of which of these two operations is done, medication in the form of cardiotonics or tonics aimed to raise the blood pressure should never be omitted.

The discussion was opened by Bedrna of Czechoslovakia, who said that there was a consensus as to the value of embolectomy during the first ten days. After this interval arterectomy had not given good results in his experience. On the other hand, in three of five cases success had followed resection of the third and fourth lumbar sympathetic ganglions. The two failures had occurred in the treatment of patients in an unfavorable general condition.

Albert of Belgium also emphasized the value of embolectomy in the early period but said that it entails the use of a perfect technique. Arterectomy at a later stage is followed by a certain degree of vasodilatation, which favors establishment of a collateral circulation. Instead of resection of the sympathetic ganglions, simple infiltration with a solution of procaine hydrochloride suffices.

Leriche of Strasbourg did not agree that the reflex arc whose afferent fibers were said to be in the tunica adventitia of the blocked artery, is as simple an affair as had been claimed. Even if it was admitted that this reflex arc exists, much could be accomplished by blocking the adventitia so that the reflex would follow a different course. He endorsed embolectomy as the operation of choice, to be carried out as soon as possible (within a few hours) after lodgment of the embolus and arterectomy in late cases. Infiltration of the sympathetic ganglions

is to be advised in preference to resection, because the patients are, as a rule, in no condition to undergo resection

Wertheimer of Lyons reported three cases which illustrated the difficulty of differential diagnosis between embolism and spasm. Infiltration of the sympathetic ganglions with procaine hydrochloride is of great value in giving relief from the severe pain as well as in distinguishing spasm from embolism.

Marc Iselin and Heim de Balsac of Paris maintained that the initial phenomenon is not the embolism. The artery ceases to pulsate, and coagulation ceases at this level. There is also relative independence between the circulation within the lumen of an artery and that in its wall. The latter does not depend, strictly speaking, on thrombotic occlusion of the artery, as those who advise arteriectomy believe.

Naulleau of Angers endorsed arteriography in the diagnosis of arterial embolism and also pointed out the importance of infiltration by procaine hydrochloride of the lumbar sympathetic ganglions. With the aid of arteriography he had been able to determine accurately the location of the embolus. Infiltration of the sympathetic ganglions should be employed as an adjuvant to embolectomy or arteriectomy.

FRACTURES

The subjects chosen for the third report were indications for operative intervention in the treatment of fractures and orthopedic methods in the treatment of closed diaphyseal fractures of the leg. The reporters were Dr. Merle d'Aubigne and Dr. Creysse of Paris and Dr. Dams of Brussels. Their reports represent an analysis of publications from many of the best European fracture clinics and particularly the experience of the largest French hospitals.

Drs. d'Aubigne and Creysse stated that the general principles to be followed are as follows: 1. The reduction should be carried out as soon as possible, to avoid later muscular contracture and edema. 2. Local anesthesia suffices in early cases. Preference is given to spinal over general anesthesia in late cases. 3. All reductions should be made under radiologic control either in the operating room or at the bedside, with facilities to develop films as close as possible to the place where reduction is made. 4. Every effort should be made to utilize mechanical means of reduction of a closed fracture.

The indications for treatment vary with the type of fracture. 1. In spiral fractures. When the patient is seen early (within the first four or five days) orthopedic reduction is nearly always possible. When the patient is seen more than two weeks after the accident, the prognosis is much less favorable. If transcalcaneal traction is not successful, and it frequently is not, an open reduction should be done. 2. In transverse or oblique fractures. For patients seen within a few days after the accident, orthopedic reduction only, under radiographic control, is indicated. For patients seen after two weeks, only operative reduction is of any avail, and osteosynthesis is necessary.

The value of any method of treatment depends largely on the special training of the surgeon in fracture work and on his organization. The orthopedic method is capable, with modern equipment, of producing perfect reduction in a relatively large number of patients if they are seen early. Simple plaster casts do not suffice as a means of maintaining the reduction in many cases of spiral fracture. Osteosynthesis with proper technique is followed by a high percentage of good results and greatly cuts down the length of treatment, at a minimum of risk of osteitis, intolerance of foreign material and disturbance of callus formation. Orthopedic methods with direct traction on the bone represent a great advance over simple plaster casts, but they greatly lengthen the period of treatment. The surgeon should have a number of methods at his disposal and not be limited to a single one.

Dams limited his report to the results obtained in using his method of keeping the fragments in apposition with the aid of stainless steel wire, as described in his monograph on osteo-

synthesis (Masson & Cie, Paris). The results were satisfactory in twenty-six patients with spiral fracture of the tibia who had been treated by bone suture.

In the discussion of these two reports on the treatment of fractures of the leg, Lambotte of Belgium stated that 90 per cent of the patients ought to be operated on within twelve or fifteen days after the accident, when the hematoma has been absorbed. He preferred external fixation of the fragments, by a method he had devised, and removed the appliance as soon as possible.

Charolanza of Italy preferred orthopedic reduction but called attention to the fact that perfect apposition does not always signify good function, and vice versa.

Leriche of Strasbourg, after trying all methods of fixation, now uses only metallic bone splints.

Fredet of Paris said that much of the criticism of bone splinting was unjust, because the splinting was done by surgeons with insufficient experience and equipment. Pseudarthroses caused by muscular interposition are much less to be feared than has formerly been believed.

Judet of Paris advocated immediate reduction on an orthopedic table under radiographic control and the application of a close-fitting cast. Transverse fractures, when once reduced, remained so in most cases, but this is not true of the oblique type. In fractures which cannot be reduced, open operation should not be delayed too long.

Twenty-one other surgeons took part in the discussion.

BERLIN

(From Our Regular Correspondent)

Oct 4, 1937

Congress of Orthopedic Society

At the Congress of the German Orthopedic Society, Dr. Baader, director of the Army Athletic School, delivered a lecture on "Physical Education and Fitness for Military Service." His talk contained comments on the recent examinations for military service (*THE JOURNAL*, June 20, 1936, p. 2171). He stated that the results of these examinations if carefully evaluated would appear less unfavorable than if hastily studied and that they by no means indicate a deterioration as against former times. In general, an earlier onset of puberty and an acceleration of growth are to be observed, and these phenomena entail various symptoms of weakness. The average height has increased, as has the number of extremely tall young men, whereas the numbers of the extremely undersized have diminished. The incidence of pedal deformities exhibits a geographic variation, such anomalies as a rule seem to be more frequent in the country than in the city, and in the lowlands as against mountainous regions. Defects of the feet are evaluated according to impairment of function and not on the basis of shape. In only 10 per cent of the men who presented anomalies of the shape of the feet was function impaired, and only 2 per cent had subsequently to be hospitalized. Erratic growth accounted for circulatory disorders in 77 per cent of the men, but only 07 per cent presented true heart disease. Physical exercise should not be carried to excess but it should surpass the stimulus threshold if it is to aid growth, namely, growth in the sense of a broadened and sturdy physique. Exercises which represent a prolonged strain are deleterious, but brief, diversified work-outs are, on the contrary, beneficial. The march with full equipment involves a prolonged strain on all the organs. Examination of a group of men that had marched 25 kilometers at as rapid a pace as possible and with each man laden with 13 Kg. of equipment, disclosed serious symptoms of overexertion, including inability properly to absorb nutriment. Such overexertion is particularly harmful to the more immature recruits and is definitely contraindicated as a form of exercise. Athletic contests such as football games, the 60 meter dash and so on constitute briefer, faster-moving types of exercise. Gym-

nastics ought to assume the form of games, otherwise the youths will become bored and not engage in the exercises with sufficient energy. The normal amount of sleep should not be curtailed. From an educational point of view, the glorification of athletic prowess by the newspapers is of questionable value.

Karl Gebhardt (Hohenlychen) suggested certain innovations in the case of residual defects following poliomyelitis. He attempts to treat old cases by an exercise therapy based on stimulation. Static fatigability is overcome by swimming in the brine bath. The most important residual defect encountered is the failure of muscular tonus, the normal control is lacking and this is more serious than the actual crippling. If additional effort is made, the healthy musculature has to be utilized. Supplementary surgery is to be considered only after several months of preliminary treatment. The intervention usually involves the sources of energy in the hip. Several muscles are transplanted to the hip, whence, by means of silk threads, the strength is conducted to the periphery.

Other papers were concerned with the campaign against defects of the foot and with orthopedic footwear. Prof. Franz Schede of Leipzig stated that fortunately the prevalence of pedal deformities was due not to hereditary factors but to environmental influence which inhibited proper development, to over-civilization. Outdoor life, going barefoot and so on can be of great prophylactic value. Factory-made orthopedic footwear he considers ineffective. A hard-soled boot restrains the muscles and weakens the foot. For the working population a more practical shoe ought to be designed, one that would not compress the toes. Other papers dealt with special orthopedic problems.

The Importance of the Electro-Encephalogram

Prof. Dr. Hans Berger of Jena, who is the inventor of the electro-encephalogram, has published a further report on his investigations in *Forschungen und Fortschritte*. In his opinion the electro-encephalogram and its greater oscillations, the so-called alpha waves, develop in man throughout the cerebral cortex and not, as Adrian of Cambridge assumes, only in the cortex of the occipital lobe. On the basis of recent observations, Berger rejects his former working hypothesis according to which the alpha waves of the electro-encephalogram were considered an expression of psychophysiologic action in the cerebral cortex. He now inclines toward the assumption (based on the results of experiments carried on with macaques by Dusser de Barenne and MacCulloch) that the alpha waves develop in the three lowest cell layers of the human cortex, the so-called corona radiata. He also has come to believe that many of the lesser, briefer oscillations of the electro-encephalogram are produced in the three uppermost cell layers of the cortex, the superficial zone. Numerous anatomic, physiologic and pathologic observations attest an especially close interrelation of the superficial zone and psychic activity. Berger has sought to establish this region as the place of origin of beta waves of from 11 to 24 angstroms. The importance of the beta waves for psychic function is evidenced by their increase under a diversity of circumstances in many mental disorders, in reaction states of the organism to certain alkaloids that influence cerebral function, and in any arrest of the attention with concomitant psychic phenomena, in fine, in any state of heightened brain action. Under the foregoing conditions the alpha waves, on the contrary, become comparatively scarce or disappear entirely. From his research in this field Berger arrived at the following conclusions. The sum total of physiologic and psychophysiologic activity in the cerebral cortex of man is expressed in the characteristic tension curve of the electro-encephalogram, which curve is the final result of the component action current originating in the particular nerve cell layers. The alpha waves of the electro-encephalogram develop in the corona radiata. They indicate a constant physiologic activity in the area, which persists even in sleep, in generalized cortical dysfunctions they exhibit manifest alterations. Certain beta waves from 11 to

24 angstroms in length, the source of which may well be sought in the cell layers of the superficial zone, parallel psychophysiologic activity within the cortex. These waves accordingly may be regarded as significant accompanying phenomena of psychic conditions.

Influence of Weather on Disorders of Eye

Intra-ocular pressure, especially that of acute glaucoma, and iritis rheumatica have heretofore been recognized as eye disorders conditioned by the weather. Dr. Hinrichs has recently demonstrated in the eye clinic of Greifswald University that meteorologic factors (the succession of atmospheric variation-strata) also influence herpes corneae. Cases of the latter disorder are most frequent in February and March. Other eye diseases the incidence of which exhibits a regular seasonal fluctuation are pneumococcal conjunctivitis and diplobacillary conjunctivitis. The first of these entities presents an easily observable spring peak and the suggestion of a summer peak. Diplobacillary conjunctivitis presents an autumnal peak. The influence of atmospheric variation-strata on the eye ought to be regarded as a sympathetic nervous reaction to as yet obscure conditions.

Marriages

- RAFAEL RODRIGUEZ-MOLINA, San Juan, Puerto Rico, to Miss Mirian Alberta Mehrof-Caballero of Bayamon, August 25.
WILLIAM BURTON CONNOLLY, Helena, Ark., to Miss Betsey Ross of Nashville, Tenn., in Sewanee, Tenn., August 21.
DONALD ANDREWS BRISTOLL, New Britain, Conn., to Miss Charlotte Emily Smith of Greenwich, September 11.
JAMES BUFORD JOHNSON to Miss Margaret Terry, both of Los Angeles, at Santa Barbara, September 25.
WILLIAM S. BETHEA to Miss Florence Emma Manning, both of Latta, S. C., in Charleston, October 11.
LEON P. FOX, San Jose, Calif., to Miss Cleo Odom of San Francisco, in Reno, Nev., September 11.
E. KING MORGAN, Brooklyn, to Miss Janet Flemming Potter of Moncton, N. B., Canada, August 11.
DEANE HUNDLEY JR., Beulaville, N. C., to Miss Sidney Davenport of Greenville, September 18.
JOHN R. CRITTENDEN, Elkton, Ky., to Miss Ora Crittenden at Morgantown, Ky., September 15.
SIMEON STANTON BAKER, La Grange, Ky., to Miss Ruth Giegendi in Louisville, August 12.
ALEX. B. SHIPLEY, Cookeville, Tenn., to Miss Virginia Gunn of Middlesboro, Ky., September 2.
RUSSELL G. HIGHTOWER, Moulton, Ala., to Miss Margaret Ross in Birmingham, October 2.
DAVID DREZ to Miss Hester Bingham, both of De Quincey, La., in Lake Charles, August 10.
JOHN FREDERICK CARY, Reedsville, Wis., to Miss Agnes Durlin of Chicago, October 9.
JOHN CONLEY, Fort Wayne, Ind., to Miss Carol Lorraine Fields of Winchester, July 17.
DWIGHT T. BOYHAM, Rockville Center, N. Y., to Miss Ruth Elizabeth Corbett, October 9.
EDWARD HERBERT JR. to Miss Virginia Piers Summey, both of New York, September 28.
OLAF M. HEIBERG to Miss Lois Shaffer, both of Minneapolis in St. Cloud, September 4.
THOMAS E. BROADIE, St. Paul, to Miss Marjorie Allen of Attica, Ind., September 7.
ROBERT F. DICKEY, Danville, Pa., to Miss Irene E. Brouse of Northumberland, June 15.
FELICIA D. SHLEPOWICZ, Chicago, to Mr. Joseph M. Koch of Granite City, Ill., in June.
PHILLIP C. HEMMING to Miss Janet R. Hawkins, both of Elgin, Ill., September 18.
DAVID J. ROBERTS, Akron, Ohio, to Miss Ellen Neff Evans of Alliance, August 17.
ABRAHAM J. COHEN, Philadelphia, to Mrs. Eugenie Hogan, October 8.

Deaths

Leonidas Le May Mial Ⓢ Morristown, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1887, member of the American Laryngological, Rhinological and Otolological Society, fellow of the American College of Surgeons, past president of the Morris County Medical Society, at various times on the staffs of the All Souls Hospital and the Morristown Memorial Hospital, Morristown, and the New Jersey State Hospital, Greystone Park, aged 75, died, August 20, of cerebral hemorrhage and arteriosclerosis

Ernest Mammen, Bloomington, Ill., Rush Medical College, Chicago, 1884, past president of the McLean County Medical Society, fellow of the American College of Surgeons, instructor in surgical diagnosis, Medical Department, St. Johns University, Shanghai, China, and community director of health education for China, 1923-1924, served on World War examining board, surgeon to the Brokaw and St. Joseph hospitals, aged 81, died, August 22, of coronary thrombosis

Curt Herbert Krieger Ⓢ Louisville, Ky., University of Louisville School of Medicine, 1925, also a pharmacist, served during the World War, clinical assistant in otology, rhinology and laryngology at his alma mater, 1929-1936 on the staffs of the U S Marine Hospital, City Hospital, St. Joseph Infirmary, Norton Memorial Infirmary, St. Anthony's Hospital, Children's Free Hospital and Kosar Crippled Children Hospital, aged 55, died, August 30, of heart disease

Daniel Samuel Hatfield, Washington, D C, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922, clinical instructor in medicine, George Washington University School of Medicine, 1923-1924, formerly director of the bureau of communicable diseases, Baltimore City Health Department, at one time connected with the U S Public Health Service, aged 40, died, August 5, of chronic myocarditis

Peter Harold Salter Ⓢ Norfolk, Neb., L R C S, Edinburgh, L R C P, Edinburgh and L F P S, Glasgow, 1885, a founder and fellow of the American College of Surgeons, past president of the Nebraska State Medical Association and Madison County Medical Society, and a founder of the Elkhorn Valley Medical Society, on the staff of the Lutheran Hospital, aged 75, died suddenly, September 17, of angina pectoris

Bradford Massey, Pocomoke City, Md., Medico-Chirurgical University of Philadelphia, 1915 member of the Medical and Chirurgical Faculty of Maryland, secretary of the Worcester County Medical Society served during the World War and in the U S Public Health Service, deputy state and county health officer, aged 48, died, August 3, of coronary thrombosis

Elijah Lumbria Mason Ⓢ Washington, D C., Columbian College Medical Department, Washington, 1901, fellow of the American College of Physicians, at various times on the staffs of the Garfield Memorial Hospital, Episcopal Eye, Ear and Throat Hospital and the Children's Hospital, aged 66, died, August 30, of arteriosclerosis and bronchopneumonia

Maurice Langon Hughes, Clarksville, Tenn., University of Nashville Medical Department, 1897, member of the Tennessee State Medical Association, president of the Black Patch Medical Society, past president of the Montgomery County Medical Society, on the staff of the Clarksville Hospital, aged 60, died, August 28, of paroxysmal tachycardia

Charles Amory Dexter, Columbus, Ga., Jefferson Medical College of Philadelphia, 1902, member of the Medical Association of Georgia and the Associated Anesthetists of the United States and Canada, aged 59, on the staff of the Columbus City Hospital, where he died, August 20, of acute nephritis, septicemia and pneumonia

Clyde Vernon Rice, Muskogee, Okla., St. Louis University School of Medicine, 1908, member of the Oklahoma State Medical Association, past president of the Muskogee County Medical Society, on the staff of the Oklahoma Baptist Hospital, aged 58, died, August 23, of coronary occlusion and arteriosclerosis

Charles Albert Wade, Chicago, Rush Medical College, Chicago, 1891 member of the Illinois State Medical Society, formerly professor of pediatrics at the Bennett Medical College, medical examiner for the Prudential Insurance Company, aged 71, died, August 18, of cerebral hemorrhage, hypertension and arteriosclerosis

Charles Sheppard Hearne, Swarthmore, Pa., Jefferson Medical College of Philadelphia, 1890, assistant demonstrator of histology, 1891-1894, and demonstrator of normal histology, 1894-1897, at his alma mater, member of the Medical Society

of the State of Pennsylvania, aged 74, died, August 17, of paralysis agitans

Harry Frederick Nolte Ⓢ Wheeling, W Va., Jefferson Medical College of Philadelphia, 1920, fellow of the American College of Surgeons, on the surgical staffs of the Ohio Valley General and Wheeling hospitals, aged 41, died, August 11, of a self-inflicted bullet wound in the head, at a camp near North Bay, Ont

William Frederick Morse, Saginaw, Mich., University of Vermont College of Medicine, Burlington, 1882, member of the Michigan State Medical Society, aged 79, formerly on the staff of the Saginaw General Hospital and St. Mary's Hospital, where he died, August 28, of injuries received in an automobile accident

George W Armes, Leitchfield, Ky., Hospital College of Medicine, Louisville, 1890, past president of the Grayson County Medical Society, formerly county health officer at one time medical director of the State Institution for the Feeble Minded, Frankfort, aged 71, died, August 30, of Parkinson's disease

Irving Foster Armstrong, Hudson, Mass., Tufts College Medical School, Boston, 1918, member of the Massachusetts Medical Society and the New England Obstetrical and Gynecological Society, served during the World War, aged 46, died, August 9, at Wells Beach, Maine, of coronary thrombosis

John Clement Justin, Palisade, N J., University of the City of New York Medical Department, 1893, at one time a member of the school board in West New York, member of the Medical Society of New Jersey, aged 68, died, August 22, in Monroe, N Y, of diabetes mellitus and myocarditis

Richard Hagan Miller Ⓢ Surg, Lieut. Commander, U S Navy, retired, Providence, R I., Jefferson Medical College of Philadelphia, 1913, entered the navy in 1916 and retired in 1926, served during the World War, aged 50, died, August 12, at Saranac Lake, N Y, of pulmonary tuberculosis

James William McGee Ⓢ Raleigh, N C., Bellevue Hospital Medical College, New York, 1888, at one time professor of diseases of children at the University of North Carolina School of Medicine, on the staff of the Rex Hospital, aged 70, died, August 10, of coronary occlusion

William Russell Scott Ⓢ Centralia, Wash., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1908, past president of the Lewis County Medical Society, served during the World War, city health officer, aged 55, died, August 25, of coronary thrombosis

Samuel Bell Maxey, Angleton, Texas, Marion-Sims College of Medicine, St. Louis, 1896, member of the State Medical Association of Texas, president of the Brazoria County Medical Society, county health officer, died, August 30, in St. Joseph's Infirmary, Houston

Simon Volet, Liberty, N Y., Long Island College Hospital, Brooklyn, 1913, member of the Medical Society of the State of New York, aged 59, on the staff of the Maimonides Hospital, where he died, August 14, of pulmonary tuberculosis and tuberculosis of the kidney

Arthur Fay Warren, Chicopee Falls, Mass., New York Homeopathic Medical College and Hospital, 1897, for many years on the staffs of the Wesson Hospital and the Wesson Memorial Hospital, Springfield, aged 62, died, August 16, of a self-inflicted bullet wound

Frederick Winslow Rice Ⓢ Boston, University of the City of New York Medical Department, 1893, formerly police surgeon for Brighton and for many years school physician of Boston, aged 71, died, August 31, at Cape Porpoise, Maine, of coronary thrombosis

Edwin Winslow Knowles Ⓢ Greeley, Colo., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1906, served during the World War on the staff of the Greeley Hospital, aged 57, died, August 21, of coronary occlusion

Charles Albert Robbins, Dixon, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1892, veteran of the Spanish-American and World wars, aged 71, died, August 29, in the Veterans Administration Facility, Hines, of cerebral hemorrhage

Robert Phill Parriott Ⓢ Des Moines, Iowa, Drake University Medical Department, Des Moines, 1898, aged 64, at various times on the staffs of the Mercy Hospital and the Iowa Methodist Hospital, where he died, August 25, of coronary thrombosis

David Wilson McCarty, Berthoud, Colo., Jefferson Medical College of Philadelphia, 1892, member of the Colorado State Medical Society, also a druggist, aged 68, died, August 15, in the Presbyterian Hospital, Denver, of cardiovascular disease

Austin D. Heller, Bethlehem, Pa., Medico-Chirurgical College of Philadelphia, 1903, member of the Medical Society of the State of Pennsylvania, on the staff of St. Luke's Hospital, aged 57, died, August 24, of tumor of the spinal cord.

John Chrisostom Murphy, New York, John A. Creighton Medical College, Omaha, 1895, medical referee of the Veterans Administration, served during the World War, aged 65, died, August 18, in the Polyclinic Hospital, of coronary thrombosis.

Ralph Phillip Jones, St. Cloud, Minn., Hahnemann Medical College and Hospital, Chicago, 1915, served during the World War, on the staff of the Veterans Administration Facility, aged 46, died, August 21, of coronary occlusion.

William Harrison Parent, Lima, Ohio, Starling Medical College, Columbus, 1888, member of the Ohio State Medical Association, on the staffs of the Lima Memorial and St. Rita's hospitals, aged 75, died, August 29, of heart disease.

Frank Benjamin Hicks, Grand Marais, Minn., Rush Medical College, Chicago, 1899, also a minister, connected with the Indian Service, aged 76, died, in August, at the University Hospital, Minneapolis, of cerebral hemorrhage.

Anson Churchill Peckham, Fall River, Mass., Dartmouth Medical School, Hanover, N. H., 1878, formerly a member of the board of health, on the staffs of the Fall River General and Union hospitals, aged 81, died, August 29.

Eugene Burdett Dyson, Akron, Ohio, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1898, on the staff of the Peoples Hospital, aged 64, died, August 13, of carcinoma of the rectum.

Harrie W. Kenfield, Hatteras, N. C., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906, aged 60, died, August 22, in the Albemarle Hospital, Elizabeth City, of carcinoma of the larynx.

James P. Letts, Romeo, Mich., Detroit Medical College, 1884, formerly village health officer, aged 80, died, August 22, in St. Joseph Hospital and Sanitarium, Mount Clemens, of injuries received in an automobile accident.

James Edward McDonald, Cohoes, N. Y., Albany (N. Y.) Medical College, 1899, formerly mayor and postmaster, on the staff of the Cohoes Hospital, died, August 14, of a skull fracture received in a fall.

William Christian Iuen, Kansas City, Mo., Medical College of Ohio, Cincinnati, 1883, member of the Missouri State Medical Association, aged 78, died, August 27, in the Trinity Lutheran Hospital, of heart disease.

John Allan Hodkins, Dayton, Ohio, Hospital College of Medicine, Louisville, Ky., 1903, member of the Ohio State Medical Association, aged 64, died, August 18, of arteriosclerosis and cerebral hemorrhage.

Albert De Bey, Orange City, Iowa, Rush Medical College, Chicago, 1884, formerly member of the state board of health, part owner of a hospital bearing his name, aged 76, died, August 5, of cardiac insufficiency.

Karl Vilhelm Arminen, Hancock, Mich., Rush Medical College, Chicago, 1907, member of the Michigan State Medical Society, on the staff of the St. Joseph's Hospital, aged 63, died, August 23, of myocarditis.

Hugo Lange, Brooklyn, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890, member of the Medical Society of the State of New York, aged 68, died, August 27.

John Wesley Sheffield, Binghamton, N. Y., Albany Medical College, 1886, member of the Medical Society of the State of New York, aged 79, died, August 9, of hypertrophy of the prostate and arteriosclerosis.

Thomas Harris Shipman, Providence, R. I., New York Homeopathic Medical College, 1876, formerly on the staff of the Homeopathic Hospital, aged 85, died suddenly, August 7, of carcinoma of the rectum.

George Henry Roth, Los Angeles, College of Physicians and Surgeons of San Francisco, 1909, head of the bureau of communicable diseases, county board of health, for many years, aged 60, died, August 20.

Robert Emory Peebles, Birmingham, Ala., Tulane University of Louisiana Medical Department New Orleans 1908, aged 52, died, August 24, in Boston, of arteriosclerotic and hypertensive heart disease.

Charles Wesley Higgins, Providence, R. I., University of Pennsylvania Department of Medicine Philadelphia 1894, for many years on the staff of the Rhode Island Hospital, aged 71, died, August 19.

William Robert Dendy, Pelzer, S. C., Atlanta Medical College, 1888, member of the South Carolina Medical Association, aged 75, died, August 27, in the Greenville (S. C.) Hospital, of heart disease.

Alfred H. Noster, New Braunfels, Texas, Rush Medical College, Chicago, 1892, formerly county health officer, aged 71, died, August 15, in a hospital at San Antonio, of carcinoma of the intestine.

Fred Abram Fowler, Tilton, N. H., University of Vermont College of Medicine, Burlington 1899, formerly member of the state legislature, aged 67, died, August 17, of chronic interstitial nephritis.

Morris S. Halperin, Brooklyn, University of Kharkov Faculty of Medicine, Russia, 1915, aged 44, died, August 18, in the Kings County Hospital of pulmonary tuberculosis and encephalitis.

Philip Newmark, Los Angeles, Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany 1891, on the staff of the Lincoln Hospital, aged 68, died, August 18.

James Patrick Edward Scott, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia 1903, also a pharmacist, aged 63, died, August 10, of coronary thrombosis.

Matthew Lee Custer, St. Louis, St. Louis University School of Medicine, 1919, member of the American Urological Association, aged 43, died, August 27, in St. Mary's Hospital.

Charles Hyneman Johnson, Camden, N. J., Jefferson Medical College of Philadelphia, 1884, member of the Medical Society of New Jersey, aged 73, died, August 31, of nephritis.

Grace Jones, Toledo, Ohio, Toledo Medical College 1900, formerly a member of the staff of the Kemper Military School, aged 72, died, August 9, of adenocarcinoma of the sigmoid.

Duke Goodman Mohler, Laurel, Miss., Louisville (Ky.) Medical College, 1894, member of the Mississippi State Medical Association, aged 67, died, August 11, of angina pectoris.

William Kirk Mathewson, Altoona, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1920, also a pharmacist, aged 47, died, August 16, of angina pectoris.

Frank Orrin Hudnutt, Nespelem, Wash., Indiana Eclectic Medical College, Indianapolis, 1890, aged 82, died, August 7, in Spokane, of hypertension and cardiac decompensation.

Edward Warren Henderson, Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891, aged 74, died, August 27, of arteriosclerosis.

Oran Welborn Ross, Dallas, Texas, Baylor University College of Medicine, Dallas, 1913, member of the State Medical Association of Texas, aged 53, died, August 11.

H. Richard Hummel, Watertown, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1887, aged 77, died, August 15, of bilateral bronchopneumonia.

James M. Goodman, Altheimer, Ark. (licensed in Arkansas in 1903), aged 69, died, August 21, in Pine Bluff, of chronic interstitial nephritis and cirrhosis of the liver.

Don La Motte Smith, Wilsonville, Neb., University Medical College of Kansas City, 1913, aged 46, was instantly killed, August 10 in an automobile accident.

Dorr Graves, Grinnell, Iowa, University of the City of New York Medical Department, 1871, aged 88, died, August 15, of cerebral hemorrhage.

Joseph Napoleon Hood, Monroe, La., Louisville (Ky.) Medical College, 1891, at one time bank president of Eros, aged 67, died, August 16.

William Adams Connell, Kansas City, Mo., Kansas City Homeopathic Medical College, 1900, aged 73, died, August 7, of coronary thrombosis.

John Joseph Hurley, Boston, Harvard University Medical College, Boston, 1903, aged 59, died, August 6, at Rye, N. H., of coronary thrombosis.

John Harris Smith, Floyd, Va., Medical College of Virginia, Richmond, 1934, aged 28, died, August 9, of a self-inflicted bullet wound.

Alexander MacDonald, Detroit, Detroit College of Medicine 1892, aged 73, died, August 4, in the Eloise (Mich.) Hospital, of heart disease.

Daniel Parris Albertville, Ala., Chattanooga (Tenn.) Medical College, 1900, aged 59, died, August 11, of pulmonary tuberculosis.

Oswin Fred Koch, Chicago, Bennett Medical College, Chicago, 1915, aged 54, died, August 25, of carcinoma of the rectum.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Griggs Great Blood Tonic—R D Grigg Gainesville Ga Composition Essentially extracts of plant drugs including a laxative with alcohol (31.5 per cent) sugar and water, preserved with a small quantity of a salicylate. Misbranded because of incorrect labeling of alcohol content and because of fraudulent therapeutic claims as an alleged cure for blood kidney and nerve diseases dropsy female troubles etc.—[N J 24689 April 1936]

Blanton's Rheumatic Salve—Four Star Mfg Co Inc Detroit Composition Essentially a mixture of petrolatum and a fat, with a small amount of wintergreen. For rheumatism pneumonia catarrh etc. Fraudulent therapeutic claims—[N J 24690 April 1936]

A I R (Asthma Instant Relief)—Health Pharmaceutical Inc Chicago Composition Essentially a petroleum oil a small amount of wintergreen an emulsifying agent and 51.8 per cent of water. Fraudulent therapeutic claims—[N J 24692 April 1936]

Almotone—Almotone Chemical Co Colorado Springs Colo Composition Essentially extracts of plant drugs including a laxative alcohol and water. Fraudulently represented as a blood purifier general tonic and preventive—[N J 24699 April 1936]

Nuxaphen—Scott Drug Co, Charlotte N C Composition Essentially calcium manganese and magnesium glycerophosphates, extracts of plant drugs including nuxvomica alcohol (8.8 per cent) sugar and water. Misbranded because the label represented the alcohol content as 30 per cent and because the stuff was fraudulently represented as a tonic, blood purifier etc.—[N J 24700 April 1936]

Owens' VIII Veg—Bakers Research Co St Louis Misbranded because the name gave the false impression that it was a vegetable compound and the further statement, health bread represented that it was good for the health, whereas it contained a potentially deleterious ingredient phenolphthalein—[N J 24963 May 1936]

Father Mollingers Famous Herb Tea—Joseph R Hite trading as Mollinger Co Pittsburgh Composition Essentially ground drugs including senna leaves bearberry sassafras bark fennel lavender flowers, mandrake couch grass anise seed and elder flowers. For blood disorders liver and stomach troubles pimples etc. Fraudulent therapeutic claims—[N J 25029 July 1936]

Father Mollinger's Prescription for Female Complaints—Joseph R Hite trading as Mollinger Co Pittsburgh Composition Extracts of unnamed plant drugs. Fraudulent therapeutic claims—[N J 25029 July 1936]

Mollinger's Original White Salve—Joseph R Hite trading as Mollinger Co Pittsburgh Composition Essentially zinc oxide (15.5 per cent) horic acid (5.1 per cent) and a small proportion of carbohc acid in a petrolatum base. For eczema tetter itch pimples old sores ulcers etc. Fraudulent therapeutic claims—[N J 25029 July 1936]

Ditman's Sea Salt—A J Ditman New York Composition Common salt (98.3 per cent) calcium oxide (0.25 per cent) and traces of magnesium and sulfate compounds. For debility rheumatism weak joints and muscles etc. Fraudulent therapeutic claims—[N J 25031 July 1936]

Lutorol—Peck & Sterha Inc New York Composition Essentially oxyquinoline sulfate (0.87 per cent) horic acid a small proportion of an aluminum compound a gum glycerin and water. For protective feminine hygiene leukorrhea etc. Fraudulent therapeutic claims—[N J 25032 July 1936]

Vichy Water Powders (Artificial)—Charles Cassese Importing Co Paterson N J Composition Baking soda (93.6 per cent) common salt and epsom salt and small packages containing tartaric acid. For stomach liver and kidney troubles etc. Fraudulent therapeutic claims—[N J 25033 July 1936]

Mrs Olsen's Valuable Salve—Mrs G P Olsen Salve Co Bayonne N J Composition Essentially rosin and petrolatum. For cuts boils old sores eczema blood poisoning ulcers etc. Fraudulent therapeutic claims—[N J 25038 July 1936]

Ferro China Doria—Charles Cassese Importing Co Paterson N J Composition A compound of iron such as iron and ammonium citrate cinchona alkaloids alcohol (13.8 per cent) sugar spices and water. For anemia loss of appetite general debility etc. Fraudulent therapeutic claim—[N J 25033 July 1936]

Jaques' Little Wonder Capsules—Theodore W Hellmers East Orange N J Composition Essentially calcium carbonate (17 per cent) epsom salt cascara sagrada extract, and an extract of an unnamed pungent drug. For indigestion stomach catarrh heartburn headache etc. Fraudulent therapeutic claims—[N J 25035 July 1936]

Pyrol—Kip Corporation Los Angeles Composition (Tubes labeled Pyrol cans labeled Anti Pyrexol) Essentially petrolatum and zinc oxide with small amounts of carbohc acid salicylic acid and essential oils including wintergreen. For burns boils piles ulcers dandruff erysipelas carbuncles etc. Fraudulent therapeutic claims—[N J 25039 July 1936]

Vin Vigorans—LeCompte & Gayle Co Frankfort Ky Composition Essentially extracts of plant drugs including alkaloids of quinine and strychnine an iron compound glycerin alcohol and water. A nerve and blood tonic. Fraudulent therapeutic claims and misrepresentation that the stuff was a wine which it was not—[N J 25040 July 1936]

Hale's Phosphate of Soda Compound—J V Hale Co Inc Boston Composition Essentially sodium sulfate (39.9 per cent) baking soda and tartaric acid with small amounts of sodium phosphate (3.6 per cent) potassium sulfate and lithium citrate. For stomach and rheumatic troubles alcoholic excesses etc. Fraudulent therapeutic claims—[N J 25041 July 1936]

Goudy's Magic Liniment—Dr Goudy Remedy Co, Charleston Ill Composition Essentially a mixture of carbohc acid extracts of plant drugs including chrysophanic acid and chrysarobin and water with 17 per cent of alcohol. For eczema dog and snake bites lockjaw 'piles' etc. Fraudulent therapeutic claims—[N J 25044 July 1936]

Slp O—McCahe Drug Co Fargo, N D Composition Essentially plant drugs menthol, tar chloroform sugar and water. For coughs bronchial asthma catarrh hay fever etc. Misbranded because of objectionable claims—[N J 25043 July 1936]

Chalgonla Tablets—LeCompte & Gayle Co Frankfort Ky Composition In each tablet acetaminid (3.25 grains) baking soda (1.55 grains) and starch. For insomnia sciatica etc. Fraudulent therapeutic claims—[N J 25040 July 1936]

Walter's Radiant Hair Rejuvenator—Walter's Products Co Inc St Paul Composition Essentially lead acetate sulfur horic acid quinine glycerin water and perfume with 14.7 per cent of alcohol. Fraudulently represented to rejuvenate the hair and restore the original color remove dandruff, cure scalp trouble etc.—[N J 25045 July 1936]

Revigoro Tonic Health Tea—Universal Pharmacal Co, Chicago Composition Powdered plant drugs including senna buchu and pipsissewa leaves camomile and elder flowers anise seed snake root squaw root, cinnamon and wahoo barks and the roots of licorice gentian sarsaparilla podophyllum and sassafras. For genito-urinary and prostatic disorders obesity stomach and liver ailments etc. Fraudulent therapeutic claims—[N J 25046 July 1936]

Slim—Slim Sales Co, Inc Cleveland Composition Dinitrophenol, 1.197 and 1.115 grains respectively per tablet in two specimens examined. For obesity. Fraudulent representations—[N J 25042 July 1936]

Lygel—Lehn & Fink Inc Bloomfield N J Composition A jelly containing essentially water and a gum with small amounts of chloride a phenolic compound and perfume. For leukorrhea cervicitis, vaginitis cervical ulceration etc. Fraudulent therapeutic claims—[N J 25049 July 1936]

Malvitose—Malvitose Laboratories Inc, San Francisco Composition About 63 per cent of sugars about 9 per cent of protein 7.9 per cent of fat and small proportions of inorganic constituents. For malnutrition hyperacidity anemia stomach ulcers tuberculosis asthma eczema etc. Fraudulent therapeutic claims—[N J 25050 July 1936]

McNess Sarsaparilla and Burdock Compound—Furst McNess Co Freeport Ill Composition Essentially sugar water and alcohol (13.8 per cent) with small amounts of sodium and potassium iodide an iron compound and a laxative plant drug. Tonic. Fraudulent therapeutic claims—[N J 25051 July 1936]

Kastor Gems—Fort Wayne Drug Co Fort Wayne Ind Composition not stated except that it was contaminated with insect excreta larvae shells and other evidence of insect infestation. Represented as Pure Castor Oil in Delicious Chocolate Bon Bons. Adulterated—[N J 25054 July 1936]

Vegex Vitamin Yeast Candy—Fort Wayne Drug Co Fort Wayne Ind Composition not stated except that it was contaminated with insect excreta larvae shells and other evidence of insect infestation. Represented as Health Food. Aids Digestion Helps Preserve Teeth Stimulates Vigor. Fraudulent therapeutic claims also adulterated—[N J 25054 July 1936]

Nyalypus—Fort Wayne Drug Co Fort Wayne Ind Composition Essentially cresote eucalyptol sugars and water. For coughs bronchitis asthma etc. Fraudulent therapeutic claims—[N J 25054 July 1936]

Anti Headache Tablets—Furst McNess Co Freeport Ill Composition acetaminid (3.28 grains) caffeine baking soda and starch. Fraudulent therapeutic claims—[N J 25073 July 1936]

Requa's Charcoal Tablets—S & S Drug Co New Orleans La and Requa Mfg Co New York Composition not stated. For stomach troubles rheumatism malaria etc. Fraudulent therapeutic claims—[N J 25047 July 1936]

Correspondence

YAWS AND SYPHILIS

To the Editor—From August 1929 to August 1931, more than 1,000 autopsies were performed in Haiti under the observation of J H Chambers, Commander, Medical Corps, U S Navy. From this group, material from more than 200 cases showing some aortic change or evidence of yaws-syphilis in other organs was forwarded to Prof A S Warthin of the Department of Pathology at the University of Michigan for further study (Chambers, J H. Review of the Pathology Observed in 1,018 Postmortem Examinations in Haiti, *U S Nav M Bull* 34 285 [July] 1936).

Professor Warthin began the study, but owing to his death the work was continued by Professor Weller. After several years of careful study two reports have been made on this material. Weller, C V. The Pathology of the Aorta in Haitian Treponematosis, *Am J Syph, Gonorr & Ven Dis* 20 467 (Sept.) 1936, The Visceral Pathology of Haitian Treponematosis, *ibid* 21 357 (July) 1937.

Few papers of greater value with reference to the pathology of yaws-syphilis have appeared than the two papers of Professor Weller. It is regretted that *THE JOURNAL* passed over both these papers in its abstracts of current medical literature. In the meantime *THE JOURNAL* has reviewed at length a paper having to do with the inconclusive experiments on laboratory animals to prove a difference between yaws and syphilis (Turner, T B. Studies on Relationship Between Yaws and Syphilis, *Am J Hyg* 25 477 [May] 1937, abstr *THE JOURNAL*, August 7, p 462). I am therefore taking the liberty of offering certain abstracts from these two papers.

From the paper on the aorta

Of the 169 aortas which were available for our study 111 or 65.7 per cent showed histologic lesions which could not be differentiated from those which in the temperate zone we are accustomed to interpret as due to syphilis.

There was but one aorta in the entire series which presented a granulomatous process of a type which was not in accord with aortic lesions as seen in our local material but since persistent staining for spirochetes gave negative results we were forced to conclude the lesion was not treponematous.

From the 111 aortas showing histologic lesions which in the temperate zone we consider diagnostic of syphilis ninety-seven were selected as having foci of sufficient activity to warrant special staining for spirochetes. In this group treponemes have now been demonstrated in twenty-nine cases. In all of these the morphology of the organism was such as to justify its acceptance as *Treponema pallidum* (or pertenuis).

Among the aortas sent there were eleven from patients who were positive in respect to both genital scar and syphilitic history but were negative for yaws scar and yaws history. Nine of these aortas showed microscopic lesions considered characteristic of syphilis and treponemes were demonstrated in five. On the other hand fourteen aortas were included from patients who were positive for yaws scar and yaws history but negative for genital scar and history of syphilis. Eleven of these showed microscopic changes which in the temperate zone are considered characteristic of syphilis and treponemes were demonstrated in one. Because of the elements of chance distribution and technical difficulty a smaller percentage of success in staining organisms in the second group cannot be considered significant. [The italics are mine and will be referred to later.]

In the 169 patients there were twelve aortic aneurysms in addition to the one previously mentioned as believed to be due neither to syphilis nor to yaws.

The foregoing extracts are sufficient to show the character of this study of pathology of the aorta. The paper is illustrated with eight plates ($\times 140$) showing the pathologic changes and eight fields ($\times 2,500$) showing one or more of the treponemes. The second paper which appeared in July 1937, has to do with the visceral pathology, and of this I quote

Heart [158 hearts examined twenty-two of which showed histologic changes like those of syphilis]. Of the twenty-two positive hearts eighteen were associated with positive histologic findings in the aorta and in four of these treponemes were demonstrated in the aortas by silver staining.

Adrenals [152 organs examined]. Histologic changes like those of syphilis in the adrenals were associated with positive findings in the

aorta in forty-two of the forty-three cases. Such close parallelism must be significant. In eleven of these treponemes were demonstrated in the aortas. The successful staining of treponemes in two adrenals by the Warthin Starry cover glass method deserves special mention. There are very few reports in the literature of the demonstration of spirochetes in the adrenals other than in congenital syphilis of the newborn. Liver. That the criteria used for the recognition of lesions as syphilitic is sound is supported by the fact that seventeen of the eighteen livers which were found positive in this respect were associated with positive aortic lesions and four of them with aortas in which treponemes were demonstrated.

Pancreas. Portions of pancreatic tissue were available in 115 autopsies. In but six of these were changes found which in our material of local origin would have received a presumptive diagnosis of syphilis.

Brain and meninges [material from twenty-four autopsies examined]. Four of the twenty-four showed changes which can be diagnosed as syphilitic.

The latter paper is illustrated with five photomicrographs showing the histologic changes and the treponemes. The two papers conclude with practically the same statement

In order to avoid misunderstanding the statement made at the close of the report upon the aorta must be reiterated. In view of the impossibility of establishing an indubitable clinical diagnosis for each patient this study must not be considered as offering certain proof of either the unity or the duality of yaws and syphilis. It is intended only as an objective presentation of factual material. However one of three conditions must exist either yaws and syphilis are essentially the same disease or the group of patients here considered has an extremely high incidence of syphilis and the evidences of this disease alone are apparent in viscera or yaws and syphilis if different diseases produce identical visceral lesions.

Professor Weller's report constitutes an epoch in the history of yaws and syphilis. The report is fair and without a taint of bias. After reading the report of Commander Chambers and noting the meticulous care with which the clinical histories of the patients were censored and the patients' statements disparaged, it would seem that the two alternate conclusions of Professor Weller were inescapable. To many who have labored in the tropics and have seriously faced the necessity on administrative grounds of finding some solution of the vexed problem, these reports will constitute the final evidence of the unity of yaws and syphilis. Considering the fact that Haiti has long been an island supposedly saturated with yaws contracted in childhood or early life, and where as high as 70 per cent of the urban population show a positive Kahn reaction, it would be difficult to assume that among these 1,018 autopsies the special material selected for this long and laborious study of yaws failed to contain yaws and that the whole study is a mere travesty. The steadily increasing evidence of the "immunity" or inoculation resistance of the one disease against the other has some bearing on the first alternate conclusion. As for the second alternate conclusion I am persuaded that we ought never to forget that yaws-syphilis is an untreated disease, among an unclean people whose skins in the hot environment of the tropics are always subject to the symbiotic effect of other parasites on their unprotected lesions. Furthermore, competent observers have reported no differences in the pale parasite of syphilis that cannot be observed in the very thin parasite of yaws. Jonathan Hutchinson, among clinicians, decided for the unity of syphilis and yaws on clinical grounds alone.

Referring now to the quotation which I have placed in italics dealing with cases showing clear evidence of yaws history and yaws scars and with no history of syphilis, and considering the wide prevalence of yaws in Haiti and the quantity of this autopsy material for a study of yaws, I have no hesitation in affirming that these cases prove the unity of yaws and syphilis. Prominent physicians advocating the present campaign against syphilis have gratuitously slandered Christopher Columbus, one of the bravest sailors of all time by publishing to the world that he was a syphilitic on less—much less "indubitable evidence" (He had been to Haiti).

Professor Weller and Commander Chambers are to be congratulated on the character of the study.

R C HOLCOMBE M D, Upper Darby Pa
Captain M C, U S Navy, retired

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PNEUMOCOCCIC ENDOCARDITIS

To the Editor—A woman aged 26 with one child living and well has pneumococcic endocarditis that came on five days after an appendectomy. I have isolated the pneumococcus by blood culture. Growth was excellent at the end of seventy-two hours; the morphology very characteristic and the organism gram positive. The Kahn test is negative. Sedimentation is markedly increased and the urine normal. The blood count is typical of an acute infection. The tonsils are out. X-ray examination of the teeth is negative and the chest is negative on physical and X-ray examination. There is a definite mitral systolic blow with a mitral regurgitation and some slight cardiac enlargement. She has been ill for five weeks now. There is a daily temperature rise to 103 F and a pulse between 140 and 160. I have not had an X-ray examination of the sinuses but the frontals and the antrums transilluminate well. There was no comment on the ethmoid. Some days there is no rise of temperature. Two weeks ago she suffered acute muscular pain and joint pain involving the right carpal and metacarpal joints, the right shoulder joint and the entire sacro-iliac joint and also the right ankle with swelling. This all subsided on large doses of salicylates and now she is free from pain. The patient has a secondary anemia now but no disturbance of the hematopoietic system. The liver and spleen are normal. There is no pleural rub. My treatment consists of absolute bed rest, a high caloric diet, iron and vitamins A, B and D and salicylates by mouth and also intravenously when a gastro-intestinal upset occurs. Is there anything else that I can offer the patient? Can one express a favorable prognosis? What relation if any did the appendectomy have to the present condition?

HENRY A. HARTMAN, M.D., Kankakee, Ill.

ANSWER—This is a most unusual situation. Acute bacterial endocarditis is almost always a complication of a bacteremia from some obvious source. In the case of the pneumococcus it ordinarily complicates pneumonia. The disease runs a rapid and fatal course without remission. It is assumed, therefore, that this must be a subacute bacterial endocarditis.

About 95 per cent of all cases of subacute bacterial endocarditis are caused by *Streptococcus viridans*. This leaves but 5 per cent to be distributed among several organisms, of which the pneumococcus is one. In addition to this a high percentage of the cases of subacute bacterial endocarditis are superimposed on an old rheumatic carditis, which apparently did not exist in this case. It is assumed that the appendectomy was uncomplicated, and if so it is difficult to see how it could have been involved, except as an innocent bystander.

There is no specific treatment for subacute bacterial endocarditis and because of its rarity no considerable series of pneumococcic endocarditis have been reported recently. It would seem logical to type this organism and use large quantities of serum if the organism is one that lends itself to serum therapy. Commercial serums against many of the types of pneumococci are available. The same precautions should be observed here that are observed in the use of the serum in the treatment of pneumonia. The prognosis is distinctly unfavorable.

DEFORMITY OF HEAD AFTER CHILDBIRTH

To the Editor—I have a patient 6 months old who has had a depressed skull laterally and posteriorly since birth. He was delivered normally, but the labor was long and dry. The mother is extremely nervous over the condition as the child's head appears much deformed. Is there anything surgically or otherwise that would offer some improvement?

PHILIP E. ZANFAGNA, M.D., Lawrence, Mass.

ANSWER—It is possible that such a misshapen head may be due to the effect of a contracted pelvis on the child's head during birth, though another possible cause would be a premature synostosis of the small sutures or a partial synostosis of the larger sutures.

If the closure and ossification are confined to the small sutures during the first months of life, the form and shape of the cranium are altered and its capacity is diminished. When the coronal and lambdoidal sutures are closed early the transverse diameter of the skull is diminished and the growth of the anteroposterior diameter is increased, constituting a so-called dolichocephalic skull.

When the coronal suture alone undergoes an early closure, an asymmetrical or distorted configuration of the skull occurs and this has been called plagiocephaly.

There may be other causes for a cranial asymmetry, for example the craniotabes of rickets which is a softening of the

flat bones, due to delayed ossification and calcification. The contour of the head may become misshapen as the result of compression of one portion or another of the softened vault of the skull. But this condition would be associated with other symptoms of rickets and could hardly be overlooked.

It is obvious from the foregoing that surgical treatment could not correct the deformity which already exists. The experience with craniectomy dates back to Lanelongue (about 1880), who advocated this operation for microcephaly. After a short period of popularity, the operation was abandoned.

A plastic operation performed on the skull would be hazardous, and the results would be disappointing, to say the least.

It should be mentioned, however, that mere asymmetry of the skull need not interfere with mental development, though on the other hand, if the cranial capacity is diminished, obviously cerebral growth would be retarded.

EPIDURAL INJECTIONS

To the Editor—Please inform me whether in giving epidural sacral injections any other substances besides procaine hydrochloride or a similar local anesthetic plus varying amounts of physiologic solution of sodium chloride have ever been used. I do know that the use of alcohol has been attempted but has been given up on account of dangerous results such as motor paralysis. What I should like to know particularly is whether such substances as paraldehyde, acetone or ether have been tried. Also what references could you give me in the matter.

EUGENE FROELICH, M.D., New York

ANSWER—There is little in the literature concerning injection into the sacral canal of the substances mentioned except physiologic solution of sodium chloride, especially when procaine hydrochloride has been dissolved in it. R. E. Farr (Sacral Anesthesia: Some Practical and Experimental Points, *Arch Surg* 12:715 [Oct] 1926) measured the quantity that could be introduced into the caudal canal until the epidural space was filled to a point at which the solution appeared at the foramen magnum and found the average amount to be about 120 cc. Alcohol has been injected intentionally and unintentionally. The results were not uniformly good enough to permit continuation of that practice. Some have attempted to incorporate procaine hydrochloride into an oily medium or into other mediums that would be less likely to be absorbed than water in the hope that the duration of anesthesia with procaine hydrochloride might thereby be extended. This is especially true in obstetric cases. Various substances have been injected unintentionally, and an extensive search of the literature might reveal case reports of the results of such injection. Some investigators have tried a few substances but have never reported their results in the literature, it would seem from this that they were not favorably impressed with the procedure.

GONORRHEA IN THE FEMALE

To the Editor—What constitute the microscopic diagnostic criteria for chronic or subacute gonorrhea in the female with involvement of Skene's glands and the cervix? What would be the microscopic picture after cure? What is the significance of pus cells alone in smears from the urethra and cervix? Given a case of chronic or subacute gonorrhea involving the cervix, Skene's glands and possibly Bartholin's glands, what treatment is indicated?

M.D. Massachusetts

ANSWER—The diagnosis of gonorrhea in the female genital tract is based on both microscopic and clinical observations. Bacteriologic evidence without clinical evidence of infection is rare, clinical evidence without bacteriologic confirmation is common. The discovery of gram-negative intracellular diplococci in smears made from the vaginal tract indicates the diagnosis. Unless the typically stained biscuit-shaped organisms are inside the leukocytes, the diagnosis is doubtful. To be absolutely certain as is necessary in research work or in medicolegal cases the physician must culture the organisms on a suitable medium such as Pelouze's. For ordinary office practice the smear suffices. It is extremely difficult to be sure that a woman is cured of gonorrhea if by cure is meant non-infectiousness. If after all clinical signs of active infection subside, gonococci are not demonstrable by smears or cultures repeated at intervals of two months for a period of twelve months, and if provocative stimulation (drinking sexual excitement) produces no clinical or bacteriologic evidence of disease, the patient is presumed to be noninfectious. Even so, the physician should beware of committing himself too definitely on this point. Pus cells alone in a smear from the urethra or cervix mean nonspecific urethritis (most often traumatic) or cervicitis. Subacute gonorrhea of the lower genital tract is best treated by complete rest in bed, sexual abstinence, avoidance of instrumental trauma and prohibition of irritating douches. Gonorrhea tends to be a self-limited disease and

often will remain localized if nothing is done to promote its ascent to the adnexa. The important point in treating acute gonorrhea of the lower tract is to avoid overtreatment. Forceful douching, the use of strong antiseptics, frequent instrumentation and digital examination almost certainly do more harm than good. Since the organisms are deeply embedded in the glands of the cervix, Skene's glands and Bartholin's glands, surface applications are useless. The vaginitis (except in children) is transitory. Heat applied to Bartholin's abscesses is comforting, later incision may be required. When the chronic stage is reached Skene's tubules may be fulgurated, Bartholin's glands excised, and the endocervical glands removed by electric coagulation or the Sturmdorf operation.

VACUOLES IN LENS A FORM OF CATARACT

To the Editor—I am a physician 30 years of age. About one year ago, after having worn glasses for about fifteen years with only occasional minor changes, my vision became distinctly worse. I also began to have frequent burning distress in the epigastrium which was only partially relieved by taking food or alkali. This distress was made worse by smoking. My third complaint which began at about the same time consisted of frequent bowel movements with a soft stool and occasional tenesmus. I have also been suffering with an easy fatigue and a desire to sleep in the early part of the afternoon. Consultation with an ophthalmologist disclosed that since the time I had seen him about two years before I had developed bilateral lenticular vacuoles. He suggested that I have a complete study with a possible metabolic disturbance in mind. His study revealed a blood pressure of 120 systolic 80 diastolic, pulse 68, red blood corpuscles 4,700,000, hemoglobin 88 per cent, white blood corpuscles 7,500, differential count normal, normal free and combined hydrochloric acid, basal metabolic rate minus 7, x-ray examination of chest negative, blood sugar combining power, urea nitrogen and creatinine normal, a moderately severe proctitis on sigmoidoscopic examination, a pylorospasm that was relieved after about a half hour of gentle massage and a marked intestinal hypermotility. There was no intrinsic gastric disturbance. The proctitis was relieved by local therapy. Sedatives by mouth and complete elimination of smoking relieved the epigastric symptoms temporarily but increased the sleepiness. Of late this epigastric burning has recurred. I have been taking small doses of alcohol, as liqueurs two or three times a day which has partially relieved me. Foreign protein fever therapy and intravenous calcium therapy were tried for a few weeks but produced no evident results. The vacuoles in the lenses are still present and I believe have increased in size. Can you offer any suggestions for further study or any ideas as to the etiology of these vacuolar changes?

M.D. New York

ANSWER—The vacuoles in the lenses technically constitute a cataract, but these are present in many lenses and often remain stationary all the rest of one's life; indeed, they may have been present before birth. They do not regularly interfere with good vision, there is no special difficulty in determining what is the best glass needed, nor is there difficulty in the use of the glass prescribed, though the opacities may interfere with vision when one is in either very bright or very dull light. In the bright light the pupil is small and if the opacities are mainly axial in position one may be annoyed by a "glare" due to the dispersion of rays of light going through the vacuoles.

There is no known definite relationship between the type of gastro-intestinal trouble described and the cataractous changes that have been found in the correspondent's eyes, and it is therefore incorrect to assume any relationship.

GLAUCOMA

To the Editor—What are the mechanics in acute and chronic glaucoma? What are the steps in anatomic changes that cause an eye to pass from normality to ordinary glaucoma and to acute glaucoma and what are the steps in the mechanics? Please omit name and address.

M.D. Pennsylvania

ANSWER—The aqueous humor, which forms in the ciliary processes, passes from the posterior chamber through the pupillary space into the anterior chamber and is drained off into the venous circulation through the spaces of Fontana in the pectinate ligament, a meshwork, that forms the inner wall of Schlemm's canal. Glaucoma never occurs in a normal eye.

In an eye with a minimal of normal outflow due to blocking of a portion of the normal exit anything that precipitates a further blocking can produce an acute attack of glaucoma. Fright or a sudden emotional strain, or a prolonged period in a dark room can cause a dilatation of the pupil. The thickening of the root of the iris that occurs with dilatation can cause the anterior surface of the iris to impinge on the pectinate ligament and cause a further reduction of outflow of aqueous and a rise of intra-ocular tension. Mydriasis from drugs can produce the same result in such an eye as one with a prodromal glaucoma but never in a normal eye.

If this state of blocking of the iris angle persists for a long time an anterior synechia, i.e., adhesion of the root of the iris to the posterior surface of the cornea, forms and causes a permanent blocking of outflow which is called chronic glaucoma.

Chronic glaucoma can also be produced by the accumulation of particles of pigment in the spaces of Fontana, which converts its normal filtering meshwork into an almost solid wall.

Congenital glaucoma or hydrophthalmos is due to the absence of the canal of Schlemm.

EPILEPSY WITH GENITO-URINARY SYNDROME

To the Editor—A well nourished and developed man, aged 31, single, has had no illness except seven years ago when he had three convulsions in fourteen hours and became unconscious during them. I did not see the patient until Jan. 10, 1937. Examination revealed the pupils equal and regular. Temperature, pulse, blood pressure, chest, heart and urine were negative. Nonprotein nitrogen was 30, sugar 60, hemoglobin 75 per cent. There was no speech defect and no Babinski reflex. The Wassermann reaction was negative. The eyes reacted to light and to accommodation. The prostate was slightly enlarged. There was no growth. The right knee jerk was very active, the left not quite so fast. There were marked tremors of the extended or relaxed fingers. He did not sway in the Romberg test. For eight months he has had pains in the lower part of the abdomen and extending down the inside of the legs to the knees. They are growing worse but are not severe enough for medication. For the past two months there has been frequent urination with no burning in ordinary amounts. One year ago he arose once during the night to urinate, now he rises two or three times. Eight years ago he worked out but after convulsions he has been kept at home to work. He is a farm boy and has always worked hard. He masturbates or did a few years ago. Please omit name.

M.D. Wisconsin

ANSWER—There are two conditions present in this case. One is a neurologic syndrome known as the convulsive state, i.e., epilepsy, and the other is a genito-urinary syndrome. The convulsive state is in all probability an idiopathic epilepsy. The parents should be questioned for a possible history of similar attacks of unconsciousness and convulsions during his infancy and early childhood. He should be placed on an anticonvulsant regimen such as sodium bromide starting with 13 Gm. (20 grains) three times daily. If after one week the patient has another convulsion the dose should be increased to 16 Gm. (25 grains) three times daily. When the amount of sodium bromide necessary to keep him free from convulsions is determined he should be kept on that dose for three years. He should be directed to take the medicine regularly. The patient should not drink any alcoholic beverages, should not climb heights, should not drive an automobile and should not swim. He can do all regular work on the farm. A lateral and antero-posterior roentgenogram of the skull should be made to rule out any abnormalities. Masturbation has no relationship to the convulsive state.

CEDAR POISONING

To the Editor—What is the possibility of cedar poisoning of the lungs predisposing to lung infections such as pneumonia and death? The patient referred to had been a clean up man and firing boilers in a single mill for two months. Cold weather came on and the patient caught cold. One week later he had bronchial pneumonia. In eight days he spit up small amounts of fresh blood and stained sputum. He gradually became weaker and sixteen days after the onset died very emaciated. The patient's mother claims grounds for suit because of cedar poisoning.

HAROLD L. HOPKE, M.D., Sedro-Wolley, Wash.

ANSWER—The term "exotic timbers" includes large numbers of woods some of which are definitely associated with a capacity for injuring exposed workmen, because of a content of alkaloids, free unsaturated resinous acids or etherial oil. In some instances severe systemic diseases may be produced but more often damage is limited to dermatoses. The list of poisonous woods includes cocobolo, cytisus, acacia, yew, juniper, satinwood, black ebony, boxwood, mahogany, redwood, rosewood, teak, tagayasan, sabicu and roko. Although cedars (*Juniperus virginiana*, *Librocedrus decurrens*) are classed as exotic woods, no information is available that exposure leads to other than dermatitis from a content of cedar oil or cedar resin. In many aspects of the wood industry a fair amount of dustiness is produced but some vegetable dust is quite incapable of producing any such state as is brought about by silica or asbestos. Nearly all wood workers suffer or may suffer from a trivial degree of irritation of the eyes and nasal passages resulting from the mechanical action of wood dust particles. Such irritation is probably not more serious for cedar dust than for pine or fir. It is conceivable that a state of sensitization may occasionally arise leading to repeated attacks of dermatitis or other anaphylactoid states from cedar dust just as is true for various other woods. However, it is not possible to entertain the theory that pneumonia may have been produced

in a patient because of some peculiar content of cedarwood dust, setting it apart from other wood dusts. In British Columbia the occupational disease compensation law provides coverage for red cedar poisoning in the lumbering industry but coverage is limited to cedar dermatitis. It is not known that any other country through specific mention in occupational disease laws has ever recognized cedarwood poisoning as a disease entity.

PROGRESSIVE ANKYLOSING ARTHRITIS OF SPINE

To the Editor—A woman aged 25 complains of pain and soreness extending almost the entire length of the spine. There is an obliteration of the normal curvature of the lumbar spine. She is unable to stand erect; she has to stand with her thighs and legs slightly flexed. She had inflammatory rheumatism eight years ago involving the right hip, knee and foot. This was complicated by endocarditis and at the present time there is mitral insufficiency. When she was 12 years of age her uncle hyperextended her back over his knee. At that time she was conscious of popping in her back and she fainted. She has been troubled with her back ever since. There has been a gradual stiffening and obliteration of the normal curvature of the back for the past eight years. At present with the patient under a deep anesthetic there is no motility in the lumbar or thoracic spine. Anteroposterior and lateral x-ray films show no involvement of the bodies of the vertebrae but the articular surfaces of the spinous processes are in various stages of involvement, some being completely obliterated by exostosis. A thorough examination reveals no source of focal infection. There is no involvement of other joints of the body. She has had two courses of intravenous stock streptococcus vaccine and many courses of massage with but little result. There seem to be two main problems in this case: one to restore normal posture and the second to stop further progress of the disease. I should like your opinion on whether it would be advisable or possible by means of open operation to loosen the joints of the spinous processes in the lumbar region sufficiently to establish a normal lumbar curvature, place the patient in a cast and allow it to ankylose in a normal posture. I should also like your opinion as to what treatment might be instituted to stop any further progress of the disease. The patient has a basal metabolism of plus 40. She has a slight enlargement of the thyroid is not troubled with excessive perspiration is not losing weight has no exophthalmos and has a fine tremor of the hands. Her blood pressure is 120 systolic, 40 diastolic and her pulse runs on an average of 84. This basal metabolic reading was taken four days after a general anesthetic. If one repeated examination the patient shows a high metabolism. Do you think thyroidectomy would have any influence on the arthritis? What effect may be expected on the arthritis from parathyroidectomy?

VERN W. RITTER, M.D., Seattle

ANSWER—The injury to the spine of this patient occurred at least five years before the onset of chronic pain and deformity. Her disability apparently dates from the attack of inflammatory rheumatism. This history suggests a progressive ankylosing arthritis of the lateral articulations of the spine.

There is no feasible operation for loosening the joints of the spine to correct deformities of this type. Some correction may be obtained by gradual extension with turnbuckles in a body and bilateral leg cast.

Vaccines in ankylosing arthritis of the spine have been of little if any value. After the deformity has been corrected as much as possible, a back brace should be applied. The diet should be rich in its calcium and phosphorus content, and vitamin D in high concentration should be added.

If repeated basal metabolic tests show this marked increase in the rate, thyroidectomy may be definitely indicated.

In spite of enthusiasm on the part of some clinicians there is no scientific evidence that a parathyroidectomy is of any value in the treatment of arthritis.

OBSTETRIC PELVIMETRY

To the Editor—What is the present status of obstetric pelvimetry? Is external pelvimetry considered to be of any value at all? Of what value are the x-rays and what particular x-ray technique is necessary? Just what procedure should be carried out in the case of a primipara before she is allowed to go into labor?

M.D. Ind

ANSWER—Studies in roentgen pelvimetry have proved that the use of external pelvic measurements for determining the size of the superior strait cannot be relied on with any degree of accuracy. It is probably true that most patients with large external measurements will possess adequate pelvic capacity and most patients with small external measurements will have limited pelvic capacity. Beyond this general statement it is unwise to classify pelvis or base operative procedure on such information. External measurements as applied to the pelvic outlet however are of greater value for here the bony parts to be measured can be readily palpated. The determination of the interspinous and diagonal conjugate diameters by vaginal touch is also useful but the true conjugate and transverse diameters of the superior strait can be determined only by roentgenometry. Under the title *Newer Aspects of Pelvim-*

etry" (*Am J Surg* 25:372 [Feb] 1937) Herbert Thoms has recently discussed the routine use of roentgenometry in primiparous patients and described the pelvic variations in 371 patients. He recommends two procedures: roentgenometry of the superior strait by the grid method and lateral roentgenometry at term. For each of these a single 10 by 12 film may be used, reducing the cost to a minimum. A description of the first procedure may be found in C. H. Davis's *Gynecology and Obstetrics* (Philadelphia, W. F. Prior Company, Inc., 1933) and the latter technique in the March 1937 issue of the *Yale Journal of Biology and Medicine* (Herbert Thoms and H. M. Wilson). There is no question that accurate knowledge of the dimensions of the bony birth canal is a valuable adjunct to obstetric procedure and that simplified and inexpensive techniques should make such knowledge available wherever scientific obstetrics is practiced.

PREGNANCY WITH DIABETES

To the Editor—A primipara in the eighth month of pregnancy, small and slim, weighing 85 pounds (39 Kg.) four months ago and 96 pounds (43.5 Kg.) now, is 30 years old. There are some signs of endocrine disturbance and pronounced hypertrophosis of the legs. During the last weeks I found slight glycosuria (green with the Benedict test), no albumin, and the blood pressure 115 systolic, 75 diastolic. The patient feels well. Her slight increase in weight is favorable. A small baby is desirable on account of the generally contracted pelvis (20-22-25 cm. but the diagonal conjugate normal). I recommended a carefully restricted diet for that reason. The blood status was normal. The blood sugar level could not be stated today. There was encountered difficulty in getting blood from the inconspicuous veins in this sensitive patient. I wish to learn whether the slight glycosuria is a simple one caused by the pregnancy (glandular or renal disturbances) and without clinical importance, which is what I think, or whether you think that a blood sugar as well as a urine sugar fermentation test has to be done and whether some danger might lurk behind the glycosuria?

M.D. New York

ANSWER—From the description it is quite possible that the reducing substance found in the urine does not represent a clinically significant disturbance of carbohydrate metabolism. However, in all fairness to the patient, further tests should be done to prove that such is the case. If the urinary reducing substance is shown to be dextrose, a quantitative estimation of the sugar in a twenty-four hour specimen of urine would enable one to gauge its clinical significance. If the amount of sugar excreted in twenty-four hours is significant, every effort should be made to obtain a blood sample for sugar determination. A microdetermination on 0.2 cc. of blood drawn from the finger tip can be done, if necessary. A comparison of the blood sugar level with the glycosuria will show whether the latter is a renal or a true diabetic phenomenon. If it turns out to be the latter, it is potentially dangerous and should be treated.

MOVING OF PATIENT AFTER CHILDBIRTH

To the Editor—Is there any danger in transporting a puerperal woman from the hospital to her home within the first twenty-four hours post partum? Specifically, the situation which prompts the query is this: There is in this city no hospital the nearest being some 20 miles distant. Many calls to homes entail a trip of 20 miles out into the country and consume many hours of otherwise profitable time which might be spent in the office. Often an entire day or night is spent for the most part needlessly at the bedside for fear to leave not knowing that one can be given timely notification to return or knowing be able to arrive in time. The practice of obstetrics is therefore becoming slowly but surely a thorn in my side which fact I regret. The hospitals in the neighboring cities will accept patients for twenty-four hours including the delivery room charges at a nominal rate which amount I would gladly deduct from the regular or usual fee in order to make it possible for the patients to go to the hospital for reasons and advantages to both patient and physician obvious and implied in the foregoing account.

M.D. California

ANSWER—There is much to be said in favor of adopting any expedient that would thus protect the patient and benefit the physician. However, there are many reasons why a patient should not be removed from a hospital to her home within the first twenty-four hours post partum, especially if this is a considerable distance. The danger of infection, either perineal or uterine, is the greatest of these, delayed post partum hemorrhage is another risk. Would not the distance to which the patient had been removed make it necessary for the medical attendant to limit his supervision and care of her during the remainder of her puerperium? His duties to her are by no means ended by her safe delivery.

A compromise in this situation outlined might solve the problem. The physician might assume the costs of the first day and the delivery room as he suggests the patient to pay her own hospital board and room for the ensuing eight or ten

days As a purely business proposition to the hospital, its management should see the advantage in cooperating by giving a nominal flat rate for these additional days, comparable to the favorable one mentioned for the first twenty-four hours

BILIRUBIN TEST OF LIVER FUNCTION

To the Editor—Please give me the details of the value of the bilirubin test as described by Louis J. Soffer (Present Day Status of Liver Function Tests *Medicine* 14: 185 [May] 1935). This is bilirubin used intravenously and it is asserted to be the most delicate test for determining impaired hepatic function. Will you please give me the details of the test as reported and its value or usefulness. I do not have the article available.

MARK H. SMITH, M.D. Hollywood, Calif.

ANSWER—The bilirubin test of liver function is one of a number described in the article mentioned. This test is a measure of the excretory function of the liver and is considered by many observers to be one of the earliest and most valuable indications of failing liver function. The test requires a fairly well equipped chemical laboratory and a knowledge of colorimetry. Its use is indicated as an aid to diagnosis in situations in which the diagnosis is not clear but there is a justifiable suspicion of cirrhosis of the liver, hepatitis, cholangitis, neoplasm of the liver or any condition that may cause destruction of liver tissue or suppress its function. It should not be employed when a hyperbilirubinemia is already present.

The following details of the test are quoted from Soffer's report:

The method used was described by Harrop and Barron (*J. Clin. Investigation* 9: 577 [Feb.] 1931), with the modification described by Soffer (*Bull. Johns Hopkins Hosp.* 52: 365 [May] 1933). A total amount of bilirubin equal to 1 mg. per kilogram of body weight is dissolved in 15 cc. of a one tenth molar solution of sodium carbonate which has previously been brought to the boiling point and then allowed to cool to 80° C. The bilirubin dissolves completely and a clear iodine colored solution is obtained. A control sample of oxalated blood is collected in a dry syringe and with the needle in situ the bilirubin is then injected intravenously. Oxalated samples of blood are obtained from the other arm within five minutes and again four hours after the injection. The concentration of bilirubin in the plasma is determined by means of the Ernst and Forster method (*Klin. Wchnschr.* 3: 2386 [Dec. 23] 1924).

The plasma is precipitated by redistilled acetone, which is used in different concentrations depending on the amount of bilirubin in the sample. Thus with the control and with the sample taken after four hours 2 cc. of acetone is added to 2 cc. of plasma while with 1 cc. of the plasma of the five minute sample 4 cc. of acetone is used. After the plasma and acetone mixtures are shaken the samples are centrifuged and filtered directly into a dry microcolorimeter cup and compared with a standard solution of 1/6000 potassium dichromate. The bilirubin content of the specimen taken five minutes after injection minus the bilirubin content of the control sample is considered as 100 per cent of the injected pigment. The percentage of bilirubin contained in the sample taken after four hours is then calculated after previous subtraction of the bilirubin contained in the control.

The following formulas are employed to determine the amount of bilirubin in the various samples:

Control and four hour specimens

$$0.329 \times 2 \text{ (dilution)} \times \frac{\text{reading of standard}}{\text{reading of unknown}}$$

Five minute specimen

$$0.329 \times 5 \text{ (dilution)} \times \frac{\text{reading of standard}}{\text{reading of unknown}}$$

The upper limit of normal retention is from 5 to 6 per cent in four hours.

TELLURIUM POISONING

To the Editor—A young Portuguese had severe abdominal pain with marked rigidity and signs of mild shock. He was found to have tellurium poisoning. He was observed for eleven weeks. Can you furnish me with any information regarding this condition especially as to treatment, prognosis and evaluation of disability. The case is a remarkably interesting one and I purposely have not gone into details because it is to be fully reported by the physicians who treated the case and did all the laboratory work at Newark City Hospital.

ANTHONY AMBROSE, M.D. Newark, N. J.

ANSWER—Tellurium poisoning and particularly industrial tellurium poisoning is so rare that its actuality is sometimes doubted. Its rarity is reflected in the fact that in the cumulative index of the *Journal of Industrial Hygiene* this item does not appear between the years 1922 and 1936. However it is generally held that a disease entity may be traced to tellurium as the specific cause. The principal manifestations are diminished flow of saliva, suppressed perspiration, insomnia and a persistent odor of garlic on the breath. It is stated that as little as 510,000 mg. of tellurium oxide will communicate to the breath the odor of garlic. While any compound of tellurium may be toxic, it is established that tellureted hydrogen is perhaps more active than any other compound and that its action may be dissimilar to other compounds in that it acts as a powerful hemolytic agent.

Dogmatic statements as to the treatment, prognosis and disability of tellurium poisoning are unwarranted because of the limited number of cases in the literature available for study. Treatment demands prompt removal from additional exposure. Pilocarpine has been used to counteract the dryness of the skin and mouth. Diuresis and catharsis are advocated. Hydrochloric acid may be administered orally to replace the deficiency of acid secretion. Chiefly the treatment is symptomatic.

Based on the experience with tellurium poisoning in industry, prognosis as to complete and prompt recovery is good. In animal experiments, large doses of tellurium have led to destruction of the mucous membrane of the gastrointestinal tract, intestinal hemorrhage, hyperemia of all abdominal organs, a parenchymatous nephritis associated with hematuria, and albuminuria. More extensive information may be found in:

Occupation and Health International Labour Office, Geneva, 1934, p. 1009.

PIGMENTED NEVI OR SEBORRHEIC WARTS

To the Editor—What is the usual course of pigmented nevi? A patient past 70 years of age is raising a crop of them on his back between the shoulders. One nevus has existed for a number of years; its dimensions are about 2 cm. long, 1.2 cm. wide and from 2 to 3 mm. in height. It is sessile, of a leathery feel, dry and smooth and has been and is at present quiescent except for an apparent deepening of the black pigment. Of recent occurrence three more, a few centimeters apart, have started as small pinkish spots coming up consecutively becoming elevated above the skin growing visibly and darkening. None are pedunculated. Textbooks make short references, e.g., stating that they appear at any age, show no retrogression or spontaneous riddance and are usually benign. Half hearted advice is given to let them alone unless sudden accelerated growth, change in coloration, bleeding, pain or breaking up and spreading occur when a malignant condition may develop. What is the nature of the tissue? Can its development be checked? The growths are unsightly and the patient worries over the possibility of increasing numbers. Does surgical removal subject him to the risk of subsequent change to malignancy? Is carbon roentgen or radium therapy thus threatening too? One young dermatologist in a kind of European manner, spoke of scraping the nevi away. Would you kindly advise me?

M. D. Illinois

ANSWER—In all probability these growths, occurring on the trunk of a patient beyond middle life, increasing locally with considerable rapidity, becoming leathery and dark brown as they age, are not pigmented nevi but seborrheic warts. On close inspection, tiny, flat topped, smooth, skin colored wartlets may be found in the same neighborhood, closely resembling young verrucae vulgares. These seborrheic warts favor the covered parts, occur usually on the trunk of adults, and some times propagate rapidly so that hundreds may be counted, the ill defined patch spreading peripherally. When fully developed they sometimes closely resemble nevi but on curettage are much more brittle, breaking easily and leaving a rough surface with bleeding points. Histologically they are characterized by a complicated acanthosis with many contorted, interpapillary pegs and papillae, cross sections of the papillae and numerous epithelial pearls giving a plum pudding-like appearance to the epithelium. The border between epithelium and corium is clearly defined.

Curettage, followed by cauterization or freezing with carbon dioxide snow, will destroy the growths. Others may develop and require later treatment, or their growth and spread may cease. They seldom become malignant.

OBSTETRIC PROBLEM IN WOMAN WITH HEART DISEASE AND HYPERTENSION

To the Editor—I was recently called to see a primipara and found her in hard labor with the right arm prolapsed through the vulva. The blood pressure was 180 systolic, 110 diastolic and the pulse 140 per minute. A regular slight cyanosis was present and there were cardinal signs of decompensation and exhaustion. There was generalized edema of the lungs with many moist rales and a respiratory rate of 34 per minute. The urine showed four plus albumin. What was the proper treatment in this case?

M. D. Louisiana

ANSWER—Many factors enter into the choice of treatment in a case like that described. The serious condition of the patient would hinder any extensive operative procedure. Treatment should at first be directed toward improving the general physical condition. This should consist of the administration of small amounts of hypertonic dextrose solution intravenously (from 100 to 200 cc. of 50 per cent solution), morphine and if necessary a cardiac stimulant. When the general condition of the patient has improved the termination of the labor can be undertaken.

The choice of treatment will depend on the size of the pelvis, the state of the cervix and the condition of the baby. In the event that the cervix is sufficiently dilated to allow for manipulation and the baby is dead, the safest procedure for the patient is a destructive operation. The prolapsed hand and forearm can be thoroughly cleansed and by means of traction on this extremity a good exposure of the chest can be obtained. The ribs presenting can be cut and the soft tissues of the chest and abdomen eviscerated. One can now pull down one or both feet and finish the extraction by doing a craniotomy on the aftercoming head. Some anesthesia will be required for this procedure.

In the event that the baby is alive, it should be given some consideration. However, an attempt to deliver a live baby will result in an increased hazard to the patient. Under deep anesthesia sufficient relaxation of the uterus can usually be obtained to enable one to pull down one or both legs. This will usually result in the prolapsed arm being automatically pulled upward into the uterus. If dilatation of the cervix is not complete, the extraction need not follow the completion of the version but complete dilatation should be awaited.

The serious condition of the patient and the increased hazards of infection due to prolapse of the arm through the vulva would preclude any question of cesarean section.

MYXEDEMA OR EXOPHTHALMOS AFTER THYROID RESECTION

To the Editor—A white married man aged 55 weighing 135 pounds (61 Kg.) a storekeeper came to me with the complaint of pronounced symmetrical swelling of both eyelids of five months duration causing him considerable annoyance and embarrassment. Questioning revealed that about a year ago he had had a thyroidectomy performed for what was apparently an exophthalmic goiter. He states that postoperatively he improved considerably and gained weight and strength until about five months ago when his eyelids began to swell. The past history and family history did not reveal anything of significance. Physical examination showed a marked symmetrical nonpitting edema of both eyelids a fine tremor of both hands and moderate exaggeration of reflexes. Otherwise there were no gross abnormalities. The laboratory procedures which included a urinalysis blood count and differential count Kahn and Wassermann tests a roentgenogram of the chest and an electrocardiogram were negative. A basal metabolism determination showed a reading of plus 34, a rather confusing factor in view of the fact that he has been taking compound solution of iodine since his operation five drops twice daily. The condition is apparently not due to angioneurotic edema conjunctivitis glaucoma or Bright's disease. I have advised a check on the basal metabolism reading and am considering incipient myxedema. Your opinion and suggestions as to treatment would be greatly appreciated.

M D Illinois

ANSWER—Myxedema is of course a possibility that must be considered. But the question does not mention whether or not there is any exophthalmos and if so whether or not it is increasing. There are a few cases in which exophthalmos develops in the course of one to five years after a well performed thyroidectomy. The basal metabolism in such cases is not a constant and may even be in the minus column. If the second basal reading is still high, it might be well to consider roentgen therapy to the thyroid in addition to administration of compound solution of iodine.

TREATMENT OF SYPHILIS

To the Editor—A healthy looking married woman aged 24 with no history or clinical symptoms of syphilis consulted me for the relief of sterility. Examination disclosed chronic ulcerative cervicitis and a four plus blood Wassermann reaction. I administered neoarsphenamine a bismuth compound mercury and mixed treatment for two years giving the usual doses at suitable intervals continuously. The cervix healed promptly but the menses grew scanty. The Wassermann reaction remained four plus for about twelve months and then gradually diminished in the strength of reaction to negative at the end of the second year. After three months of rest from all treatment the Wassermann reaction again showed two plus. Is the patient clinically cured? If so why the return of the positive Wassermann reaction? What treatment should be pursued further? Why the almost complete suppression of menses in a few months after the treatment was begun? I curetted the uterus at the beginning. Could this have caused the change in the menses? During the three months rest period I gave injections of theelin. Could these have caused the Wassermann reaction to show plus again?

M D Illinois

ANSWER—It is not possible to say that this patient has been adequately treated for syphilis, because the number of doses and the amounts of the various drugs are not given. It appears probable that she is not clinically cured and that she needs more treatment with arsenic and preparations of a heavy metal, preferably bismuth. No mention is made of the examination of the spinal fluid. This should be done. The menstrual change

was probably caused by the curettage and not the antisyphilitic treatment. It does not seem possible that the injections of theelin could have had anything to do with the return of the positive Wassermann reaction.

UNILATERAL ERYTHEMA OF FACE IN INFANT

To the Editor—A baby girl 10 months old was delivered with a mid forceps operation and did not show any ill effects from it. The cry was spontaneous the baby fed well and there was no evidence of any birth injury. The baby has since been in good health the weight and length being up to standard and the general physical examination negative. However when the child was about 3½ to 4 months of age the mother first began to notice a red flush on the right cheek and ear, which has been present daily ever since. This is an erythema not of the blotchy type but it covers the whole cheek and ear and looks as though the child had been exposed to the cold air for a time. The left cheek has never been thus affected. This is more noticeable after the child has been up and about for a while or has exercised by crawling so that there are times during the day when the cheeks appear about the same. The child sleeps on both sides and as far as I can find out there is no clothing or other irritant that is causing this. What would be your opinion as to the etiology of this marked difference in the two sides of the face? If it is due possibly to a nerve injury at birth what is the prognosis? Can you suggest anything further in order to make a diagnosis?

DRAPER LONG, M D, Mason City Iowa

ANSWER—Discovery of the cause of the unilateral erythema of the face described in this question would necessitate a further inquiry into the history of the infant.

Erythema in its simplest form is usually a vasomotor disturbance. It occurs frequently in infants and children and is due to the instability of the vasomotor system. Such an erythema in an otherwise healthy infant may be caused by crying, by pressure from lying on the cheek, by sunburn from sunrays or quartz lamps, and by frost-bite from exposure to cold. A child sensitive to wool or silk might by lying on a pillow or blanket of such material show an erythema of the cheek.

Similarly, some food product to which the infant is sensitive might cause such an erythema. Foods introduced at about the fourth month, such as cereals, vegetables, orange juice or cod liver oil, might be suspected. Finally, the rash might not be a true erythema but a diffuse hemangioma which became noticeable at about the fourth month of life.

NODDING SPASM OR HEAD NOD

To the Editor—A woman aged 59 the wife of a minister has complained of a tremor of the head nodding in character, for the past several months. Associated with this is a left sided tinnitus most apparent while lying in bed. The neck muscles feel stiff. Examinations are essentially negative from an objective point of view except that her blood pressure is 158 systolic 88 diastolic. She is very nervous and worries a great deal about the tremor because her mother had a similar condition during the latter years of her life and she wonders whether a similar state of affairs is going to exist in her for the rest of her life.

M D Ontario

ANSWER—The patient has what is known as "nodding spasm" or "head nod." This condition is due to either one of several conditions. These are (1) senile nod associated with cerebral arteriosclerosis, (2) familial head nod and (3) head nod due to a cerebellar tumor. The prognosis in the first two is poor, so that if there is no objective evidence of any cerebellar tumor the head nod of the patient will in all probability remain as it is or increase in amplitude.

MEASURING BLOOD PRESSURE

To the Editor—In taking blood pressure in a person with variation of pulse volume is it correct to take the systolic reading at the point where one begins to hear a few beats (for example only one in three beats is heard) or where all the beats are heard?

E W Young M D, Cambridge N Y

ANSWER—The systolic tension in pulsus alternans, whether the alternation in force is regular or irregular, is variable with the different cardiac contractions. Certainly the point at which one hears the first sounds should be taken as the level of the maximum systolic tension and the pressure at which all the pulsations are first heard as the minimum systolic tension. In these instances the diastolic tension is rarely variable to any appreciable degree. In recording the arterial tension in such cases the systolic tension is best recorded as being within a range rather than as a single figure, for example 180 140/105. The finding of fluctuating pulse pressure such as described is evidence of grave cardiac disease and one must be more concerned with the cardiac capacity than with the exact momentary level of the systolic tension.

Book Notices

Annual Review of Biochemistry Edited by James Murray Luck. Vol. 11. Cloth. Price \$5. Pp. 708. Stanford University California Annual Review of Biochemistry Ltd. 1937.

The sixth volume of these collected reviews, which have become almost indispensable to those interested in keeping abreast of recent developments in biochemistry, maintains the high standard of previous years. The present issue is further improved as a reference book by inclusion for the first time of an excellent subject index, the editorial committee indicates that a cumulative index covering the earlier volumes will be published later. This will remedy a really serious deficiency. The subjects covered in the present reviews include permeability, biologic oxidations and reductions, enzymes, microchemistry, chemistry of carbohydrates and glucosides, lipins, steroids, proteins and amino acids, sulfur compounds, nucleic acids, purines and pyrimidines, metabolism of carbohydrates, fats and proteins and amino acids, detoxication mechanisms, hormones, vitamins, nutrition, biochemistry of muscle, metabolism of brain and nerve, biochemistry of fish, chemical embryology, plant pigments, alkaloids, photosynthesis, mineral nutrition and organic acids of plants, biochemistry of bacteria, and immunochemistry. Thirty-five authors, many of them new to the Annual Review, from institutions in both Europe and America have contributed to this book. It is, of course, not feasible to review in detail so extensive and diverse a series of articles. Among them several deserve special praise, especially the article by G. F. Marrian and G. C. Butler on the hormones. These authors are to be commended for their critical commentary on a subject in which slovenly thinking, careless, poorly controlled work and rank commercialism have left a deep imprint on the practice of medicine. A number of other sections, such as those on vitamins, nutrition, detoxication mechanisms, immunochemistry, steroids and alkaloids, should be of special interest to clinicians.

K ycheniyu o ganglionevromakh tsentralnoy nervnoy sistemy [By] A. M. Antonov. Seriya doktorskiykh dissertatsiy dopushchennykh k zashechitu v Saratovskom Gosudarstvennom Meditsinskoy Institutu v 1935 36 uchebnom godu [Study of Ganglioneuromas of Central Nervous System. Series of Doctors Theses Obtained at Saratov State Medical Institute in 1935-36.] Paper. Gratis. Pp. 205 with illustrations. Saratov Izdanie Saratovskogo Gosudarstvennogo Instituta. 1936.

Antonov presents a critical study of forty-six cases of so-called ganglioneuromas of the central nervous system collected from universal literature, together with a detailed histologic study of his own two cases. He concludes that evidence adduced in favor of the ganglionic nature of the large cells in cases of ganglioneuromas of the central nervous system cited, based on the morphology of the nucleus, the presence of the nucleolus and the size of the cells, is inadequate, since the same morphologic criteria hold true in the case of the large glial cells. The sole presence of "typical" ganglionic cells containing Nissl bodies and neurofibrils does not determine the nature of the neoplasm, since ganglionic cells as well as the neurofibrils are characterized by remarkable persistence and may remain preserved as pre-existing cells and fibers in the case of a growing glioma. In order to prove that the typical ganglionic cells are a part of the blastomatic growth of the neoplasm, one must present positive evidence of their multiplication, and that has not been done in the cases cited. New formation of nerve fibrils, either medullated or nonmedullated, has not been demonstrated in gangliomas of the central nervous system. Such nerve fibers as are found in them are either those which have persisted or those which have been newly formed from the surrounding healthy nervous tissue. The forms of mitosis of nuclei described by the various authors as taking place in the large cells of the ganglioneuromas are characteristic of cells of glial rather than of ganglionic origin. The author believes that the formation of polynuclear giant cells with "deformed" or "grotesque" nuclei proceeds by way of asymmetrical, multipolar and essentially abortive karyokinesis. He insists that for the determination of the nature of a neoplasm it is not only essential to establish the character of the giant cells, be they ganglionic or glial but it involves a study of the morphology of the tumor as a whole and particularly of its embryonal cell. The presence of spongioblasts in a tumor determines the

nature of the entire neoplasm as a spongioblastoma. The author suggests the following classification of spongioblastomas: (a) spongioblastoma simplex (uniforme) for the tumors consisting predominantly of spongioblasts and not characterized by polymorphism of cellular elements, (b) spongioblastoma multiforme for tumors characterized by polymorphism of cellular elements without, however, the predominance of polynuclear giant cells (fibrillar astrocytes), (c) spongioblastoma multiforme astrocytare for tumors characterized by polymorphism of cellular elements with a predominance of polynuclear giant cells. Antonov concludes that all the cited cases of ganglioneuromas of the central nervous system were in reality tumors of glial nature predominantly polymorphous spongioblastomas. The second and third cases reported by Schmincke, the case of Paul, of Watjen and of Smirnov, were cases of spongioblastoma multiforme astrocytare, while the cases of Robertson, Behlunger and Otfried Foerster were astrocytomas. The author further expresses his doubt as to the ganglionic nature of certain neoplasms of the sympathetic nervous system and of the adrenals described as ganglioncuromas. He believes that in all probability these tumors are likewise of glial origin.

The Development of Cardiac Enlargement in Disease of the Heart. A Radiological Study. By J. H. Palmer. Medical Research Council Special Report Series No. 222. Paper. Price 1s. Pp. 49 with 58 illustrations. London: His Majesty's Stationery Office. 1937.

This small monograph of work emanating from the Cardiac Department of the London Hospital and carried out under the supervision of Dr. John Parkinson is an important contribution on the utility of x-ray examination in heart disease. The monograph contains an analysis of the development and prognosis of cardiac enlargement in approximately 200 cases of the more common types of heart disease. It is based on the direct superposition of successive cardiac outlines traced from tele-roentgenograms taken with carefully standardized technique. Among other things, it was concluded that (a) a residue of cardiac enlargement persists following prolonged bouts of congestive failure, (b) the position of the diaphragm is important in determining the apparent size of the heart, (c) enlargement was usually an involvement of all heart chambers, although certain valvular lesions tended to favor the enlargement of particular chambers, (d) the distribution of the enlargement to all chambers of the heart is aided by the restraining action of the pericardium, (e) coronary narrowing with myocardial ischemia may often cause otherwise unexplained progressive enlargement of the heart, and (f) stabilized hypertension by itself does not cause progressive cardiac enlargement. This short monograph merits careful attention not alone for the factual data contained but because it points the way by which careful objective evidence may be accumulated and used in the evaluation of cardiac disease.

Clinical Allergy. By Louis Tuff. M.D. Chief of Clinic of Allergy and Applied Immunology, Temple University Hospital, Philadelphia. Introduction by John A. Kolmer. M.D. Dr. P.H.D. Sc. Professor of Medicine, Temple University, Philadelphia. Cloth. Price \$3. Pp. 111 with 82 illustrations. Philadelphia & London: W. B. Saunders Company. 1937.

The author states in his preface that the book was intended primarily for the general practitioner, medical student and beginner in the field of allergy. The contents and organization of this work render this claim too modest. The book is suitable for general practitioners and beginners, and it avoids the fault found in previous similar works of attempting to write for the public as well as for the physician. The terms peculiar to allergy are defined in a lucid manner characteristic of the entire book. Lengthy reviews and conflicting opinions are avoided wherever possible. An excellent summary closes each chapter. In addition to these advantages in a work intended for the general practitioner, it condenses and organizes the recent literature on allergy so well that most specialists in the field will welcome it.

The subject is divided into four sections. 1. The fundamental principles of allergy and anaphylaxis, including the principles of diagnosis and treatment, are considered in 122 pages. The review of the principles of anaphylaxis and of allergy is excellently written, a difficult subject done in a clear, simple manner. The colored illustrations of skin and conjunctival reactions are well chosen. 2. The etiologic types of allergic reactions, such

as serum sickness, drug allergy, food allergy, pollen allergy, bacterial allergy and physical allergy, are adequately treated in separate chapters in another 122 pages. 3 The next 188 pages are devoted to the characteristic clinical manifestations of allergy, with particular emphasis on perennial and seasonal allergic rhinitis and asthma. This section is especially well illustrated with reproductions of roentgenograms of the lungs with and without the use of iodized oil. 4 The allergic dermatoses, including the urticarial dermatoses, atopic dermatitis and contact dermatitis, are included in a separate section. This section is of special value not alone to the general practitioner and allergist but also to the dermatologist. It is an excellent summary of the literature to date, with special emphasis paid to Sulzberger's well known work in this field. The final part of the book lends itself less to good organization. A chapter is devoted to allergy in pediatrics. Another discusses the relation of allergy to the various specialties. Finally, the appendix contains much valuable and practical information with no attempt at organization. This includes the methods of preparation of routine and special materials, the method for doing quantitative pollen surveys, an excellent detailed method for an environmental study, a list of the various allergens and their sources, and an adequate group of elimination diets.

Einführung in die chemische Physiologie. Von Dr. E. Lehnartz, a. o. Professor an der Universität Göttingen. Paper. Price 18 marks. Pp. 420 with 66 illustrations. Berlin: Julius Springer, 1937.

This introductory work, if thoroughly mastered, would result in a rather intimate acquaintance with the subject in question. The author begins with a descriptive account of the chemical groundwork of the body and proceeds to a functional treatment of the dynamic chemistry of vital processes. The selection of material is judicious and the work is well balanced. The author apologizes in his preface for not being able to include references to the original literature. In the body of the text, however, he proceeds to mention names, without references, of investigators of particular fields. In this he betrays a common failing by mentioning thirty German and central European names to ten of all other nationalities in approximately twenty pages taken at random for a test count. This is an unfortunate and insidious tendency of many writers of all groups, but it should certainly be guarded against in science, which, of all human activities, should maintain racial and national impartiality. The excuse that students unable to read foreign languages could not benefit by the citations is invalid here because references are not given in any case, and there is only the question of fairness in assigning credit for scientific progress. Certain diagrammatic representations are uncritical and inaccurate, for example, that of blood sugar regulation on page 294. There is convincing evidence that muscle glycogen cannot directly supply dextrose to maintain a falling blood sugar. The formulas and diagram for the mechanism of urea formation (p. 325) are unwarrantedly positive at the present stage of our knowledge. As a whole the work is interesting and generally accurate. The price \$8 for a textbook of 420 pages is exorbitant in comparison with similar American works, one of the best of which sells for \$4

Blackwater Fever. A Historical Survey and Summary of Observations Made Over a Century. By J. W. W. Stephens, M.D., F.R.S. Cloth. Price 15s. Pp. 727 with 2 illustrations. Liverpool: University Press of Liverpool. London: Hodder & Stoughton Ltd. 1937.

The author has attempted the tremendous task of giving a complete review of blackwater fever from its first recognition as a distinct condition until the present. The mass of literature would make this difficult, but in addition the task is all the more complicated by the lack of any true understanding of the etiology of the disease and the consequent lack of rational and controlled observations relating to its causation and cure. The main part of the book is divided into twelve chapters, of which four are concerned with etiology and the remaining with synonymy, geographic distribution, history, symptoms, treatment, prognosis, prophylaxis, blood, urine and feces, and pathology. Under each chapter the author has collected collated brief excerpts and concise reviews of all available literature, arranged for the most part in chronological sequence. The author points out that many data are of unequal value, but he has refrained from expressing his opinion on their ultimate value and has left

the records to indicate their frequently contradictory nature. Of particular importance is the fact that at the end of each chapter there is a short review giving the author's conclusions regarding the literature. A series of twenty-six appendices gives various additional data on the subjects treated in the main text and other materials bearing on the blackwater problem. In view of the relation of quinine to blackwater fever the author has devoted a series of these appendices to his notes on the history of Peruvian bark, the history and use of quinine and various data on quinine in relation to blackwater. Although this is not a consecutive, readable account of this disease, it will unquestionably be considered one of the most accurate, complete and scholarly compilations of source materials relating to any of the diseases of man. The book will be a practical necessity for all workers interested in this important disease whether they are clinicians, research workers or medical historians.

Preoperative and Postoperative Treatment. By Robert L. Mason, A.B., M.D., F.A.C.S., Assistant in Surgery at the Massachusetts General Hospital. Cloth. Price \$6. Pp. 495 with 123 illustrations. Philadelphia & London: W. B. Saunders Company, 1937.

The past decade has seen the development of an extensive literature on preoperative and postoperative treatment, and doubtless the advances in the postoperative management of surgical patients the surgeon owes in large measure to the physiologist and to the maintenance of better hospital records. No other single volume has so completely and so accurately covered these subjects and left so little in dispute. Beginning with methods of appraisal of operative risks, surgical patients with heart disease, hypertension, nephritis, diabetes, choice of anesthesia, and general methods of preoperative preparation, the author devotes the bulk of the volume to postoperative therapy. Of particular significance are chapters on shock, blood transfusion, water balance, acidosis and alkalosis, paralytic ileus, disruption of the abdominal wound and postoperative peritonitis. One recognizes a sound understanding of and deference for physiologic principles, particularly in the chapters on water balance, acidosis, shock and similar problems involving physiologic chemistry. There is an amazing amount of detail and care in the presentation of all subjects, and certainly the material is well abreast of contemporary literature. The text is profusely and well illustrated with photographs, charts and drawings. This volume represents a major contribution to surgical literature.

Die Gastroskopie. Lehrbuch und Atlas. Von Prof. Dr. Kurt Gutzelt, Direktor der Medizinischen Universitäts-Klinik Breslau, und Doz. Dr. Heinrich Teltge, Direktor des Städt. Krankenhauses am Urban, Berlin. Half leather. Price 56 marks. Pp. 342 with 207 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1937.

This splendid work is based on 5,000 gastroscopies, carried out in two German hospitals. The collaboration of the two authors has led to some contradictions. In the chapter on the indications for gastroscopy the statement is made that gastritis, as a result of gastroscopic research, now can be diagnosed in some cases according to its clinical aspects alone, in the clinical sections, however, it is pointed out with some emphasis that even now the diagnosis of chronic gastritis without gastroscopy is impossible. The technical section, describing the instruments and the special technic, is not entirely satisfactory. The advice to use not only flexible gastroscopes but also rigid instruments is especially dangerous. The authors believe that gastroscopy should be carried out only by the well trained expert, but they overlook that its use spreads so rapidly that it is impossible to tell who may be considered sufficiently trained. If dangerous rigid instruments instead of safe flexible ones are recommended, gastroscopy will share the fate of esophagoscopy and will not become that routine method of examination it should be in the study of gastric diseases. The clinical section is a contribution made valuable especially by 155 colored pictures, which are not grouped together as one usually finds but glued separately into the text. This new arrangement permits an easy comparison between text and pictures. The excellent description of gastric diseases is amplified by numerous case histories. The chapter on gastritis occupies seventy-two pages. Such rare conditions as tuberculosis and leukemia of the stomach are carefully described. Unfortunately, the authors have disregarded the extensive gastroscopic literature and have omitted important

and well observed pictures such as syphilis and lymphosarcoma of the stomach. Of special value is the appendix on the "causes of gastritis," based entirely on gastroscopic examination. It contains observations on gastritis in diabetes, nephritis, allergy and the various infectious diseases. This book should be read not only by the gastroscopist but by every clinician who is interested in gastric diseases and who is able to understand the authors' rather difficult German.

Chetvertaya venericheskaya bolezn bolezn Nikola I Favra. Sbornik pod redaktsiei prof. I. D. Perkhelya i prof. M. G. Khoroshina. [Fourth Venereal Disease: Nicolas Favre's Disease.] Odessky Gosudarstvenny Dermal Venerologicheskii Institut. Boards. Price 4 rubles. Pp. 155 with illustrations. Odessa, 1937.

This Russian work presents several papers based on the study of 153 cases of venereal lymphogranuloma treated at the institute between 1928 and 1935. The observations recorded are much the same as those observed in our clinics. The authors point out the preponderance of the disease in the male (85 per cent) and the occurrence of abortive and asymptomatic forms, particularly in women. The reaction of Frei was found to be of great practical importance in the diagnosis of difficult cases. All their cases of esthiomene (genito-anorectal elephantiasis) were preceded at some time, usually long past, by lymphogranuloma. The reaction of Frei was positive in twenty-four of twenty-five cases. The disease was far more predominant in women. Best therapeutic results were obtained from roentgenotherapy followed by surgical intervention. The authors consider genito-anorectal elephantiasis as a stage of the fourth venereal disease.

Tuberkulez legkikh i yavloniya narusheniya bronkhialnoy prokhodimosti. Atelektaz i emfizema. Pod redaktsiei Prof. S. A. Reynberga. [Pulmonary Tuberculosis and Disturbance of Bronchial Permeability. Atelectasis and Emphysema.] Cloth. Pp. 113 with 185 illustrations. Moscow & Leningrad: Gosudarstvennoe izdatel'stvo biologicheskoy i meditsinskoy literatury. Leningradskoe otdelenie, 1937.

This volume, in Russian, contains a series of roentgenologic studies, animal experiments and clinical observations aiming to elucidate the incidence and the role of bronchial obstruction in the pathogenesis of various diseases of the lungs, but particularly in pulmonary tuberculosis. Bronchography in the living patient, postmortem bronchography, and bronchoscopy will, in the opinion of the authors, broaden our knowledge of the morphology and physiology of the bronchial tree and of the tuberculous process. The authors concede the priority of the concept of bronchial obstruction as a factor in the pathogenesis of pulmonary diseases to American workers (Jackson, Coryllos and Birnbaum). It appears from their observations that bronchial obstruction is a frequent if not constant phenomenon in atelectasis and emphysema. They were not, however, able to support Coryllos's theory of pneumonia, since in their studies the bronchi were never found to be occluded in that condition.

To Drink or Not to Drink. By Charles H. Durfee. Ph.D. Cloth. Price \$2. Pp. 212. New York & Toronto: Longmans Green & Co., 1937.

This interesting and lucid book on the "problem drinker" deals with but one aspect of the problem of addiction to alcohol. The author does not undertake to discuss those diverse pathologic mental problems associated with chronic alcoholism.

The book consists of eleven chapters, the last being a dissertation on the archaic attitude of the general public toward alcoholism. The popular conception of the chronic alcoholic addict has been one of condemnation. The moral issue, with its indignant attitude and vindictive outlook, stands in paradoxical relationship to the opinions of poets and philosophers who have sung through the ages of the joys of drinking. These paradoxical attitudes represent forms of individual rationalization and probably bear a relation to the popular concepts respecting individual responsibilities involving choice of behavior.

The problem drinker cannot be understood or satisfactorily treated, or his condition ameliorated or prevented through an emotional outlook that is influenced by a spirit of vindictiveness or maudlin sympathy. With the foregoing premise in mind, the theme of this volume is perhaps expressed in the author's own words: "Modern therapy of alcoholism takes its stand on practical grounds. Its effort to change conduct unlike the miracle methods of old are based on the hypothesis, confirmed by both research and common sense, that the behavior of an

individual is the interaction of himself and his circumstances. If we recognize alcoholism as a symptom of some difficulty of the whole man and deal with it realistically we rob it of its terrors and offer freedom and happiness to countless harassed problem drinkers."

The author expresses the hope that the book may be of value to the family physician, the clergyman, the welfare worker and the public administrator, and all who come in contact with the drink problem. It is obvious that many family physicians are consulted from time to time concerning the best methods of approaching the problem drinker who is detrimental to himself and those nearest and dearest to him. In the use of this little book, serious consideration might be given to the possibility of its being placed on the family physician's reading list for prescription to the problem drinker and those who come in contact with him, since the book affords many passages to stimulate reflection applicable to the drinker himself.

Laboratory Manual of General Physiology. By T. Cunliffe Barnes. D.Sc. Assistant Professor of Biology, Yale University. Paper. Price \$1. Pp. 116 with 9 illustrations. Philadelphia: P. Blakiston's Son & Co. Inc., 1937.

This manual was evidently designed to supplement the author's "Textbook of General Physiology" but can be used equally well independently. There are references accompanying most of the experiments to the original literature from which they are derived. While written for students in general biology, many of the experiments are easily adaptable to the laboratory in medical physiology. The directions are brief and concise. The subject matter covers such subjects as surface tension, ionic interaction, acid-base balance, colloids, enzymes, plasmolysis, amoeboid and ciliary movement, permeability, and then in a series of nicely selected, simple experiments, the physiologic functions of complex organisms are considered. These include respiration, circulation, muscle and the nervous system. However, one feels that such a work is not complete without more consideration of correlating mechanisms and of nutrition. Throughout the text there are parenthetical references to sources of special chemicals and other materials used in the experiments. Both medical students and instructors will find the book valuable for reference.

Studien über das Zusammenspiel von Hypophysen und Ovarialhormonen. Insbesondere im Lichte von Parabioseversuchen. Von Ejnar Møller Christensen. Paper. Pp. 157 with 59 illustrations. Copenhagen: Levin & Munksgaard, 1935.

This is a detailed presentation of original work by the author on the effects of hypophysectomy and castration on various functions in the rat. These were studied chiefly through the agency of parabiosis. The technique of hypophysectomy and parabiosis are considered at length, that of the latter is illustrated by reproductions of photographs. Many photomicrographs showing histologic changes in various organs are included. Three really beautiful color plates illustrating normal and pathologic cellular detail of the pituitary are appended. Endocrinologists will find this a valuable acquisition to their libraries.

Injuries and Diseases of the Hip. Surgery and Conservative Treatment. By Fred H. Albee. M.D., LL.D., F.A.C.S., Chairman, Rehabilitation Commission of the State of New Jersey. Assisted by Robert L. Preston, M.D., Associate in Orthopedic Surgery, Columbia University (New York Post Graduate Medical School). Cloth. Price \$5.50. Pp. 298 with 100 illustrations. New York: Paul B. Hoeber, Inc., 1937.

This volume is chiefly valuable as a reference work on surgical procedures specifically adapted to the hip joint. The text and illustrations are taken largely from previously published works of the author with revisions and additions, approved methods of other writers also are included. One chapter is devoted entirely to a detailed description of the armamentarium of the surgeon for hip work, the next chapter deals with surgical anatomy and landmarks, preoperative preparations, and approaches to the joint. The discussion of clinical entities including pathology is brief, usually following a definite outline. A bibliography which is selective and usable rather than complete is provided. The book is ostensibly written for the benefit of the undergraduate and graduate student but probably will be appreciated more by the specialist for its detail of surgical technique.

Les méthodes chirurgicales du traitement de l'angine de poitrine. Evolution et résultats. Par Marcel Bérard. Préface par le P^r René Leriche. Paper. Pp 389. Paris. Masson & Cie [n d]

This is an excellent review of the results of surgical treatment of angina pectoris. No one has reviewed the literature so thoroughly as has Bérard, a pupil of René Leriche, one of the pioneers in the surgery of the sympathetic nervous system. The book emanates from Leriche's clinic in Lyons and reports the experiences of that clinic with this type of surgery. In addition, the author has traveled widely in Europe and also in this country, making a critical comparison of the pioneer work at Lyons and the efforts along these lines of surgeons elsewhere. Particular attention is paid to the work done in this country by White, Cutler, Beck and others. The author, although not a man with a large personal operative experience, gives an impartial view of the various operations as practiced by surgeons throughout the world. Bérard's book stands as a valuable contribution in a very specialized field and is highly recommended for those who have a reading knowledge of French.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Narcotics Constitutionalality of Harrison Narcotic Act—Section 2 of the Harrison Narcotic Act, in part, makes it unlawful for any person to sell, barter, exchange or give away opium or coca leaves or any compound, manufacture, salt, derivative or preparation thereof except in pursuance of a written order of the person to whom such drugs are sold, bartered, exchanged or given away, on a form to be issued in blank for that purpose by the commissioner of internal revenue. An indictment, said the U S circuit court of appeals, ninth circuit, charging a physician with unlawfully selling, bartering, exchanging and giving away, neither in pursuance of any written order nor in the course of his professional practice only, of a stated amount of morphine sulfate and cocaine by means of a prescription, sufficiently charges a violation of section 2 of the act. There was no merit, said the court, in the physician's contention that the Harrison Narcotic Act is an unconstitutional attempt, under the guise of taxation, to regulate purely intrastate matters. While doubt with respect to the constitutionality of the act was expressed by the Supreme Court of the United States in *U S v Daugherty* 269 U S 360, subsequent amendments have made it a genuine taxing act, thus removing any doubts of its constitutionality. *Alston v U S*, 274 U S 289, *Nigro v U S*, 276 U S 332. The circuit court of appeals, therefore, affirmed the conviction of the appellant physician—*Mauk v United States*, 88 F (2d) 557.

Malpractice Evidence of Medical Witness Necessary to Prove Negligence—The plaintiff severely injured the left side of his face and was attended by the defendant. Alleging that the treatment given by the defendant was negligent, the injured man sued him. At the conclusion of the plaintiff's evidence the trial court directed a verdict for the defendant and judgment was rendered thereon. The plaintiff then appealed to the court of civil appeals of Texas.

No physician or any person with expert knowledge testified in this case. The plaintiff testified that after his injury he suffered severe headaches, had double vision in his left eye and was able to work only for short periods of time. All the witnesses testified that the plaintiff had an ugly scar on the left side of his face, that his left eye was sunken and that the left side of his face was lower than the right side. But there was no evidence in the record that the defendant committed any overt act of negligence, nor was there any testimony that the treatment of the injury was not such as practiced by the average physician and surgeon in that particular locality. Certainly, the court said a layman could not say that any particular method of treatment practiced by a physician in a given case was proper or improper. It was contended that the failure of the defendant to use x-rays in the diagnosis of the plaintiff's

injury was negligent, but there was no testimony that the defendant owned an x-ray machine or that one was available in that locality that might have been used by him. Unquestionably, the facts showed that the physical condition and appearance of the plaintiff underwent a material change for the worse, but there was no evidence to show that this change was other than the natural result of the severe injury. In a case of this character, the court said, only medical testimony is legally competent to establish negligence, malpractice or unskillfulness on the part of the defendant and that such negligence, malpractice or unskillfulness was the proximate cause of the plaintiff's condition. In view of this lack of evidence, the trial court committed no error in directing a verdict for the defendant and the judgment entered thereon was affirmed—*Davis v Grissom (Texas)*, 103 S W (2d) 466.

Malpractice Failure to Recognize Septic Condition of Crushed Hand—Herbert Zimmerman, 9 years old, crushed his right hand in a washing machine wringer, August 1, leaving an open wound. The defendant treated the injury by swabbing it with ether and by baking. Alleging malpractice on the part of the physician, the boy and his father instituted separate actions against him. Verdicts in each action were returned for the plaintiffs but the trial court allowed motions for a new trial in each case on the sole ground that there was not sufficient evidence to warrant the verdicts. The plaintiffs appealed to the Supreme Judicial Court of Massachusetts.

There was evidence, the court said, which, if accepted by the jury in its aspects most favorable to the plaintiffs, had a tendency to show the following. On August 8, the boy's mother, seeing the injured hand unbandaged for the first time, observed what she thought was pus near the index finger, but the physician assured her that it was not pus. Shortly afterward the mother informed him that the boy had a temperature of 100 F to which the defendant observed "Oh, that is nothing." He continued the same treatment. About August 16 a hemorrhage occurred, which, according to medical evidence, was caused by infection having destroyed a blood vessel. The defendant put on a tourniquet and after taking a roentgenogram he told the parents that "sloughing there has washed the entire tendons away now, and soon we will have to operate." He did not operate sooner because, he said, "that is the chance I took." A second hemorrhage occurred a few days later, after which another physician operated. At that time there were raw surfaces from which pus exuded and the hand was swollen. A digital artery was found "eroded" along its entire length and tendons were found sloughed and destroyed from sepsis. The operation consisted in the removal of the sloughing tissue as a preliminary to further curative treatment. Later, other operations were necessary for skin and tendon grafting. The boy never recovered full motion of the index finger. There was much evidence, the court said, to contradict or to qualify that which has just been stated. But there was also evidence that during the course of the treatment the defendant, in talking to the mother, spoke of the boy's condition as not being serious, that up to and after the first hemorrhage he tried to dissuade her from calling in another physician whom she preferred, that when the mother pressed the defendant for the truth about the infection having destroyed the tendons, he replied "Well, I will take care of it," "Well that is true. I should have operated on him. That is the chance I took." "It is done now, and that is all there is to it. I will take care of it and you needn't worry about him. You needn't worry about expense, I will make good for everything."

We are of the opinion, said the Supreme Judicial Court, that from the evidence presented at the trial, including the admissions of the defendant, the jury could find that the defendant failed to exercise the skill and care which it was his duty as a physician to exercise toward his patient, in that he failed to discover the septic condition of the boy's hand, or failed to recognize its seriousness, and failed to give or to procure proper treatment as promptly as he should have done. The defendant contended that the evidence disclosed no ascertainable consequences resulting from any failure on his part which might not have followed from so severe an injury even if he had been in no way remiss. We think, however, said the court, that from the progressive nature of the infective process, in

which time may well be an important element, and from the evidence that the defendant's treatment after active infection set in was not proper and that infection was arrested when the treatment was changed, it cannot be said as a matter of law that there was no proof that delay in proper treatment was injurious in some degree, even if it only retarded ultimate recovery. Besides, if the jury believed the defendant made all of the admissions as stated, they could infer therefrom more than a recognition of harmless mistake on his part. They could infer an acknowledgment of all the necessary elements of legal liability for damages in some amount.

The Supreme Judicial Court accordingly reversed in each case the order of the trial court allowing the motion for a new trial and ordered the verdicts of the jury to stand—*Zimmerman v Litch* (two cases) (Mass.) 7 N E (2d) 437

Animal Experimentation Validity of Ordinance Authorizing Distribution of Impounded Dogs to Medical Schools and Hospitals—The city council of Chicago in 1931 passed an ordinance providing for the appointment by the commissioner of police of a poundmaster to have charge of the care of all animal activities of the department of police and authorizing the poundmaster to destroy humanely, or otherwise dispose of, any animal impounded in pursuance of the ordinance. The ordinance further provided

Whenever any reputable institutions of learning hospitals or their allied institutes in the city of Chicago shall make application to the Commissioner of Health for permission to use humanely unclaimed impounded animals for the good of mankind and the increase of knowledge relating to the cause prevention control and care of disease the Commissioner of Health on being satisfied that the said animals are to be so used shall request the Commissioner of Police to surrender said animals as applied for by the said institutions of learning hospitals or their allied institutes and thereupon it shall be the duty of the Commissioner of Police to cause said animals to be surrendered by the Poundmaster to said institutions of learning hospitals or their allied institutes for said uses

The Illinois Anti-Vivisection Society, incorporated under the laws of Illinois as a nonprofit organization, and one George D. Patterson, a citizen of Chicago, a taxpayer and an officer of the society named, instituted proceedings to restrain the city from disposing of dogs in the custody of the poundmaster to the various institutions of learning, hospitals, and the allied institutes as proposed in the ordinance. The University of Chicago, Northwestern University, Chicago Medical School, University of Illinois, Michael Reese Hospital and Loyola University were permitted to become parties defendant in the proceedings. The circuit court of Cook County, Ill., dismissed the petition for an injunction and the petitioners appealed to the appellate court of Illinois, third division, first district.

The petitioners contended that unclaimed animals in the custody of the poundmaster were public property, having an intrinsic value both while alive and when dead, and that a disposal of them under the provisions of the ordinance was a gift of public property to private persons and institutions without warrant or authority of law, that the ordinance passed by the city council did not give all citizens the same right to obtain dogs. It was contended that dogs at the rate of 1,000 a month were being delivered pursuant to the provisions of the ordinance free of charge to institutions of learning, hospitals and their allied institutes, notwithstanding that there were others ready, able, willing and desirous of purchasing the dogs but were deprived of that right under the terms of the ordinance.

The ordinance was passed by the city council under authority of section 80 of the Cities and Villages Act—*Illinois Revised Statutes of 1935, c 24 par 65 (80)*. This act by its provisions permits the city council to pass an ordinance to provide for the appointment of a board of health, and to provide by such ordinance regulations necessary to promote health and the suppression of disease in Chicago. The purpose of the ordinance in question, said the court was to promote health and the suppression of disease to make provision whereby disease may be studied in its various forms for the benefit of the public. It seems to have been conceded that the Illinois Anti-Vivisection Society was not a proper party to be joined as plaintiff in this action and that society was dropped as a party plaintiff. With respect to Patterson's right to maintain the

action, the court considered it necessary to determine whether he, as a taxpayer, had suffered a special injury by the operation of the ordinance. Just what special injury he had sustained was not readily discoverable from the allegations of the bill. He complained as a taxpayer and citizen of the unlawful diversion of public property, and charged that his property was subject to greater taxes than he would otherwise have to pay if the dogs were disposed of for a consideration, that the dogs were public property and as a taxpayer he was entitled to the benefit that might accrue to the city by the proper disposition of the dogs for financial remuneration. But, said the court, this was a general allegation and did not indicate that Patterson suffered any special damage. In the absence of allegations showing special injury, the trial court acted properly in dismissing the complaint. The decree of the trial court was therefore affirmed—*Illinois Anti-Vivisection Soc et al v City of Chicago* (Ill.), 7 N E (2d) 379

Accident Insurance Death from Overdose of Apomorphine—The insured being "more or less intoxicated," his wife, a trained nurse, caused to be administered to him by another nurse a "double dose" of apomorphine to make him sleep and to sober him up. The amount administered was an overdose and the insured very shortly thereafter died as a result of it. It was the opinion of the supreme court, appellate division, fourth department, New York, that the death was accidental and that there was "evidence of such accidental death by a visible wound on the exterior of the body," the wound being caused by the hypodermic needle. The court did not think it necessary to determine whether a voluntary taking of an overdose of apomorphine would be considered accidental. In this case the hypodermic injection was administered by another person and the administration of the overdose was accidental so far as the insured was concerned—*Cummings v Phoenix Mut Life Ins Co of Hartford, Conn* (N Y), 294 N Y S 644

Accident Insurance Death Following Voluntary Act as Death from "Accidental Means"—Two policies issued by the defendant insurance company provided double indemnity if the insured should die from bodily injury sustained through external, violent and accidental means. The insured was pregnant and was taken to the delivery room in a hospital and prepared for delivery in the usual and customary manner. Preparatory to delivery a small amount of ether was administered. When she inhaled the ether she vomited, the vomitus entered the trachea and she was asphyxiated. The insurance company resisted payment of the double indemnity, claiming that since the insured voluntarily submitted herself to a parturition operation and voluntarily inhaled the ether, her death was not the result of accidental means within the provisions of the policies. The voluntary nature of the act, said the Supreme Court, appellate division, New York, does not exclude either accidental means or accidental results in fixing liability based on accidental cause in the case of injury or fatality not designed or expected. "Accidental means" are those which produce results that are not their natural and probable consequences. The court, therefore, reversed the judgment of the trial court for the insurance company and entered judgment for the plaintiff—*Burch v Prudential Ins Co of America* (N Y), 294 N Y S 458

Current Medical Literature

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Absence of Peptic Ulcer in Pernicious Anemia—Kahn reviewed the charts of 840 patients with pernicious anemia admitted to nine hospitals during a period of fifteen years. This disease was chosen because of the known absence of free hydrochloric acid in the stomach. Of these, 616 had at least one analysis of their gastric contents and none showed the presence of free hydrochloric acid. Thus it is fair to assume that the remaining 224 patients, or at least a high percentage of them, had achlorhydria. In none of the 840 patients with pernicious anemia was a diagnosis of chronic peptic ulcer made during the time that they were in the hospitals, and in only two was there any history at any time of an ulcerative lesion of the stomach. The results of the study indicate that hydrochloric acid in the stomach may be of significance in the pathogenesis and persistence of peptic ulcer. If it is found, as a result of other surveys of this kind, that chronic peptic ulcer rarely or never develops in a patient with pernicious anemia, it may be safe to infer that at least normal acidity, or perhaps hyperacidity, is one of the conditions necessary for the development of chronic peptic ulcer. In another type of anemia, chlorosis, in which there is hyperchlorhydria, the incidence of peptic ulcer is said to be high. Many instances of chronic peptic ulcer are associated with chronic hypertrophic gastritis.

Therapeutic Procedures for Typhoid Carriers—Elsom and her colleagues made a study of twenty-two typhoid carriers, twelve of whom were later treated by the method of Gulbrandson (roentgen therapy) and two by cholecystectomy. In all but one, who was a urinary carrier, cultures of the duodenal contents before treatment showed typhoid organisms, and the function of the gallbladder was impaired as determined by x-ray examination. Radiation was entirely ineffective in eradicating

the infection. Cholecystectomy, on the other hand, was followed by relief from infection in each instance.

Treatment of Arthritis with Artificial Fever—Stecher and Solomon present the results that they obtained in twenty patients suffering from acute nonspecific infectious arthritis who, in addition to fever therapy, were given rest in bed and acetylsalicylic acid as indicated. Not only did 60 per cent of the twenty patients make complete, prompt recovery and 40 per cent have partial relief, but the duration of the disease was shortened in all, its severity decreased, the incidence of damage to the joints lessened and the damage that did occur minimized. These results compare favorably with those which have been reported in cases of gonorrheal arthritis treated with fever therapy. The twelve patients receiving complete relief had arthritic symptoms from one to ten weeks before fever therapy was instituted. These patients received from two to twenty-five hours of fever (105 F) for relief (average 7.3 hours). The eight patients having only partial relief had arthritic symptoms from two to sixteen weeks before fever therapy was instituted. This group received from five to thirty hours of fever (average seventeen hours). Five of the six patients showing x-ray evidence of damage to the joints were of the group of longer duration, indicating the importance of prompt therapy. Although the treatment of acute infectious arthritis with artificial fever must be regarded as empirical, its use is not without precedent.

Irradiation of Amenorrhea and Sterility—After treating 128 amenorrheic and sterile women with x-rays and observing them and their children over an extended period, in some instances ten years, Kaplan is still of the opinion that in no other field of gynecology is irradiation more helpful and promising than in cases of functional disturbances of the ovary and in sterility. He has had but one untoward effect in which instance treatment was administered when there already existed an embryo in utero. The effect of x-rays on the embryo is profoundly different from the effect on unimpregnated ova. Follow-up records were obtained in 114 of the 128 patients. The fourteen patients that could not be traced are regarded as failures. The menses were regulated in seventy-six women and in fifty-two there was no improvement. The oldest patient treated was 45 years of age the youngest 19. In all instances some form of endocrine therapy had been used previously and

proved unavailing. Of the 128 patients treated, forty-three were treated for amenorrhea varying from months to years, forty-one for amenorrhea and sterility, eleven for sterility alone, and thirty-three for oligomenorrhea, the menstrual intervals being several months. In all instances treatment consisted of roentgen irradiation to the ovaries. In eighty cases an additional treatment was given to the pituitary and in five instances also to the thyroid. The dose given was from 75 to 150 roentgens to a field, one treatment a week for three weeks. Occasionally a fourth treatment was administered. Of the seventy-six patients in whom menstruation was reestablished, forty-four became pregnant. Of the forty-four patients who conceived, two are at present in the course of their pregnancy, seventeen have conceived more than once, five conceived but aborted, and two of these aborted twice. Thirty-six patients became pregnant and went to term, giving birth to forty-seven living children and one stillbirth with an abnormal fetus. Of the forty-four pregnant patients, amenorrhea existed from one month to fourteen years and sterility from one to eighteen years. Only four patients had previously borne children, three had previously aborted or miscarried. None of the patients treated were harmed in any way. In no case did menstruation cease or become scanty. A study of the surviving children shows them all normal, both physically and mentally. Reports from the parents have in no instance disclosed any abnormality or any physical deformities. The oldest child under study is now 10½ years of age.

Episacroiliac Lipoma—Ries observed a woman who was operated on for tubal pregnancy in 1917, for left salpingitis, hemorrhoids and anal fistula in 1929, and who came for examination in April 1936 because of disabling pain in the back extending to the right hip and thigh which woke her up in the morning and lasted all day. It was increased by bending over. She also complained of painful menses with discharge of clots, leukorrhea, headaches, constipation and varicose veins in both legs, which were painful at times. Examination of the sacral region showed a 3 by 2 cm elliptic tender tumor placed transversely over the lower end of the right sacroiliac joint at about the point of the lateral dimple. It was elastic and of the consistency of a fatty tumor. A smaller tumor, also tender, was found over a symmetrical point on the left side. The patient declared that these tumors were the seat of her pain in the back. On repeated examination the patient located her backache consistently at these two points. May 20, 1936, the tumors were removed through two small incisions with practically no loss of blood. The patient reported freedom from pain at once. An examination of 1,000 persons at random in dispensaries, hospitals and otherwise was undertaken in order to find whether similar cases existed and had been overlooked. There were 250 males and 750 females examined. Of the 1,000 persons examined, 309 had backache in the lumbosacral region, 159 of these were without any tumors, but 317 had similar tumors. Of the 317 with tumors, forty-six were males and 271 females, that is, 18.4 per cent of the males and 36.1 per cent of the females examined showed tumors. Patients with these painful tumors recognize the area as the seat of their pain immediately, and the pain is elicited promptly by handling, pressing or moving the tumor. In some patients pressure on the episacroiliac lipoma is not only painful but causes pain to radiate from the tumor. The two characteristic dimples in the sacral region are the most favored sites of these growths. Most of those found were within 5 cm of either dimple. None of the persons examined (except three) had any knowledge of their tumors and therefore none could give information about the length of time they had had them. But if the symptom of severe backache which was referred to the episacroiliac tumors can be taken as a guide, these patients had suffered from them for years. The treatment of the episacroiliac lipomas has been by injection or by excision. Injection of 2 per cent procaine hydrochloride with or without epinephrine into the tumor or around and under it has been a simple way of relieving the pain. The relief has been strikingly rapid especially in cases of long standing in which many kinds of other treatments have been administered. The result in a number of cases has lasted for weeks. In the case of rather large tumors or in which relief from injection has been only temporary the tumor or tumors

have been excised, usually under local anesthesia. It has always been a simple matter to peel out the tumor from the surrounding tissue. Some twenty patients have so far been treated surgically by excision or injection.

Rapid Method for Estimation of Bismuth in Urine—For the rapid estimation of the bismuth content of urine Hanzlik and his associates outline the following procedure. Ten cc of urine is put in a long test tube (3 by 20 cm), one tablet (0.4 Gm) of potassium permanganate and 2 cc of concentrated sulfuric acid are added (heating will produce foaming), this is gently boiled over a microburner for about two minutes, one tablet (0.4 Gm) of oxalic acid is added (decolorization will take place and the solution should be allowed to cool) one tablet (from 0.01 to 0.04 Gm) of sodium sulfite and sodium sulfate and one tablet (0.05 Gm) of sodium iodide are added (the fluid will become yellowish green if bismuth is present) and then it is matched with the color scale, the test tube being held against the white margin above the standards. If for an occasional specimen complete oxidation does not take place, indicated by

the presence of some tint the procedure from the second step on should be repeated. The final oxidized solution must be clear as water for the proper matching of colors. The long oxidation color method and the method described were applied simultaneously to 344 specimens and the short method alone to about 1,000 specimens. The comparison showed that the short clinical method described is as accurate as need be for use in control of medication with bismuth for syphilis and probably for most clinical purposes. Although greater accuracy can be achieved with it, when desired by using more color standards instead of interpolations and complete collections of urine instead of an assumed average volume, the added inconvenience occasioned by these refinements is not warranted for ordinary purposes. It has proved useful in controlling oral medication with bismuth to make routine examination of weekly urinary specimens.

Secondary Macular Atrophy—Scull and Nomland observed twelve cases of secondary macular atrophy, seven of which occurred in association with syphilis, two with lupus erythematosus and two with acrodermatitis chronica atrophicans. In one case the associated disease was not known. Clinical activity of an associated disorder, such as syphilis, seemed to have no relation to microscopic signs of activity in the secondary atrophic lesions. About half of the biopsies of the atrophic lesions revealed no activity, and the changes that were present might be termed ghosts of former lesions. The atrophic macules occurred independent of the associated eruption, and in a case of secondary syphilis with macular atrophy there was no evidence of exanthem near the atrophic lesions. The following conclusions are drawn. Secondary macular atrophy is the result of subclinical destruction of the elastic tissue by an inflammatory infiltrate, and however diverse the accompanying disorders may be they have in common an inflammatory infiltration in the cutis, which gives rise to the usual clinical lesion.

"Valley Fever" and Fungus Coccidioides—Four of the five patients having valley fever followed by infection with Fungus coccidioides that Dickson cites were exposed to infection in the San Joaquin valley, the fifth in a laboratory when he was working with Fungus coccidioides. In all the onset of illness was characterized by pulmonary involvement with fever, cough and sputum. In case 1, in which the time of exposure to the infecting organism is accurately known, symptoms of pulmonary involvement began just nine days later. In four cases in which x-ray examination of the chest was done, the x-ray diagnosis on first examination was tuberculosis. It was only after the shadows in the roentgenograms cleared so rapidly that the roentgenologists questioned their diagnoses. All but one of the patients had erythema nodosum. In three patients the nodules appeared from thirteen to twenty-five days after the onset of illness and were accompanied by from 3 to 7 per cent eosinophils in the blood. One patient had two attacks with an interval of six weeks. In two cases the sedimentation rate was taken at the height of the disease and showed, respectively,

31 and 32 mm in one hour. None of the patients died. Two of them are apparently free from active coccidioides infection after seven years. One of the two who had the acute illness fifteen months ago is apparently well, the other developed secondary lesions in the skin of the neck, which healed under treatment and in the cervical lymph nodes. The fifth patient is recovering. The author believes that these cases prove conclusively that Fungus coccidioides is sometimes the cause of a symptom complex of acute illness which, as far as he can learn, has not been reported. It is identical with what has been known locally in the San Joaquin valley as "valley fever." Among fourteen consecutive patients with advanced coccidioid granuloma who were admitted to Kern County Hospital in 1935, three gave histories of having had valley fever. The acute disease appears to be the immediate result of initial infection with Fungus coccidioides, the organism which long has been associated with coccidioid granuloma. The author has suspected for some time that coccidioid granuloma is a secondary manifestation, which results when organisms which have lain dormant within the body for variable lengths of time eventually gain access to the blood stream and are disseminated to outlying local areas or throughout the body, thereby causing local coccidioid lesions in the skin, joints or elsewhere, or generalized coccidioid infection. Initial infection is evidently primarily through the respiratory tract in the majority of cases, but no clinical evidence of primary infection of the lungs has been collected.

Plasma Cell Myeloma and Hyperproteinemia—A patient with an unusually high blood protein, showing autohemagglutination, hemorrhages and renal insufficiency, was found by Schumacher and his associates to have at necropsy a diffuse myeloma of plasma cells, associated with minor changes of the bones. The protein present in the blood was unstable in character and coagulated readily on exposure to air. From histologic changes found in the brain and heart, spontaneous coagulation occurred in the blood stream some time before death. The actual tumor present was distributed throughout the bone marrow, with only a few clinically demonstrable lesions in the skull. Although increased plasma proteins and the accompanying manifestation of autohemagglutination may be found in conditions other than multiple myeloma, their presence should lead to careful x-ray studies of the bones to rule out this condition. The frequency of hyperproteinemia in multiple myeloma cannot be determined until adequate chemical studies have been made in all cases. It also appears to be equally true that its diagnostic specificity cannot be estimated until adequate studies of the blood protein have been undertaken in patients having a more or less generalized disease of the bones and bone marrow.

Bone Regeneration Following Maggot Therapy—Simon and his associates employed maggot therapy in fifty-five cases of severely comminuted compound fractures. Some of the compound fractures were complicated by the loss of bony tissue, but excellent regeneration followed maggot therapy. If the laceration of the skin is of sufficient size, no further opening is necessary. In the case of infected gunshot fractures and those in which the skin opening is small, an incision is made in the superficial tissues, roughly comparable to the area of bony comminution. No debridement is done and no attempt is made to remove any fragments of bone save those grossly detached. If gross hemorrhage is present, the wound is packed with petrolatum gauze for twenty-four hours. No antiseptics are used for cleansing the traumatized skin, muscle or bone. The surrounding skin is generally swabbed with ether and covered for from 2 to 3 inches about the wound with petrolatum gauze. A thin layer of sterile gauze is placed in the depths of the wound, dead spaces being eliminated when possible. Under aseptic precautions a massive dose (approximately 5000 in number representing about 1 cc of fly eggs) of twenty-four hour old maggots from 2 to 3 mm in length is removed from the sterile bottle with gauze and laid on the gauze covering the bottom of the wound. A dressing of sterile gauze from 4 to 6 inches in thickness is then applied. The maggots immediately enter the traumatized area in search of food. In response to the action of the larvae, a copious amount of thin, dark brown exudate pours from the wound and it is necessary to change the superficial layers of the gauze dressing covering the wound. The maggots mature in from twenty-four to forty-eight hours. Their removal from the wound is accomplished by removing the entire gauze dressing at the end of forty-eight hours, for, when the maggots are fully fed, they migrate from the wound into its covering. Comparatively few remain. They, in turn, may be removed by the later change of dressings. Generally speaking, none remain at the end of seventy-two hours. In contaminated but not infected lacerations, no pus or at the most, but little pus is noted and fine, clean pink granulations rapidly appear. Grossly infected wounds are cleansed of the dirty, heavy, gray granulations present, the discharge of the pus is diminished, and the odor is not quite so offensive. In this type of wound maggot implantations are necessary usually at intervals of from ten to fourteen days in contrast to intervals of from fourteen to twenty-one days in the simple contaminated wounds. Occasionally one single dose of maggots has been sufficient. The maggots loosen all nonviable bone fragments making their removal a simple matter during the dressings.

Treatment of Acute Bursitis by Needle Irrigation—Patterson and Darrach used an irrigation method in the treatment of sixty-three cases of subdeltoid bursitis. In quizzing the patients no relationship between bursitis and a previous infection was elicited. The equipment for irrigation consists

of two 18 gage steel needles $2\frac{1}{2}$ inches long, one 20 cc syringe, 60 cc of a 1 per cent solution of procaine hydrochloride, a hypodermic needle, one number 10 Bard-Parker blade and as much saline solution as thought necessary (usually about 60 cc). With the hypodermic needle and procaine hydrochloride a small wheal is made in the skin over the point of maximal tenderness. The skin is nicked through the epidermis. In like manner a second point is infiltrated about one-fourth inch posterior to the greater tuberosity of the humerus on a level with the superior facet. Following the injection of the procaine hydrochloride, one of the large needles is introduced through the cutaneous incision in the anterior portion of the anesthetized region. The point of the needle is directed posteriorly and upward toward the under surface of the acromioclavicular joint. The needle is then pushed deeper and, after it has reached a depth of from one-half to three-fourths inch the wall of the bursa can be felt as a definite resistance. A quick stab places the point of the needle within the bursa. Following the placing of this anterior needle, a second one is inserted into the region just posterior to the greater tuberosity about one fingerbreadth below the acromioclavicular joint. The needle is pushed gently down to the superior facet of the greater tuberosity and actual bone is felt with the tip of the needle. Then the needle is slowly withdrawn for about one-eighth inch and the tip of the needle is pointed in the direction of the assumed position of the tip of the anterior needle which is in the bursa. After this needle has been inserted for about one-half inch, the bursa is entered and 2 cc of procaine hydrochloride is used in each of the needles on the way down to the bursa and on going through the bursal sac. As soon as the two needles are in place, the syringe is filled with physiologic solution of sodium chloride and this is pushed through one needle to flow out the other. Usually, as soon as one syringe of saline solution has been pushed through, the patient states that the acute pain has disappeared. The bursa is washed clean with the saline solution. The needles are withdrawn and a small sterile dressing is applied to the region of the shoulder. Following this, the patient can usually move the arm freely in all directions without pain. As little saline solution as possible should be allowed to exude into the surrounding tissues. If this is prevented, the patient's arm will not be sore the following day. After the irrigation the arm is placed in a sling and the patient is allowed to go home and told to use the arm and move it only when he feels like it. No haste is made, with the result that on about the fourth to the sixth day the patient has full use of the arm without pain. Irrigation was most successful in acute cases without history of previous attacks, in cases in which the calcium, as seen in the roentgenogram, was not dense, round or bone-like and in cases in which the acute pain was localized and did not radiate.

Vitamin C Therapy in Poliomyelitis—Jungblut discusses his results with the administration of vitamin C in poliomyelitis in monkeys. A group of 181 monkeys was infected intracerebrally with amounts of virus ranging from 0.01 to 0.05 cc

of a 10 per cent suspension of virus. At different intervals following infection treatment was begun with daily subcutaneous injections of from 5 to 100 mg of natural vitamin C for a period of two weeks. Of eighty-nine monkeys treated on the first or second day of infection twenty-six survived, of fifty-three monkeys treated on the third day of the infection twenty-three survived, and of thirty-nine monkeys treated on the fifth day of the infection nine survived without showing any evidence of paralysis. A group of 101 monkeys was infected intracerebrally with amounts of virus ranging from 0.05 to 1 cc of a 10 per cent suspension of virus. At different intervals following infection, treatment of these animals was begun with daily injections of from 5 to 100 mg of synthetic vitamin C for a period of two weeks. Of twenty-five monkeys treated on the first day of infection two survived without showing any evidence of paralysis, of twenty-six monkeys treated on the third day of the infection five survived and of fifty monkeys treated on the fourth and fifth day of the infection four survived. A control group of ninety-eight monkeys was infected intracerebrally with the same amounts of virus and remained untreated. In this group only five animals survived without showing any evidences of paralysis.

Inclusion Bodies in Measles—Broadhurst and her co-workers demonstrated measles nigrosin staining inclusion bodies in the nasal membranes and in the Koplik spots in the buccal cavity. These inclusion bodies may be seen on the first day of the disease, but they seem to be uniformly present from the second day of the disease to at least the twelfth day. The inclusion bodies characteristic of measles are not present in persons who do not have measles or other virus infections. The presence of inclusion bodies is accompanied by definite erosion and changes of disintegration in the host cells. Similar

changes are seen in the lymphocytes present in the Koplik spots, as well as in the white corpuscles of measles patients.

Fibrinolytic Activity of Hemolytic Streptococci from Throats—Of 203 throat cultures from 133 apparently normal persons, and of twenty-eight cultures from twenty-eight patients who were under the care of a physician because of low grade infections of the throat, Jolly and her associates found hemolytic streptococci in 118 and twenty-seven, respectively. The fibrinolytic activity of the latter strains was slightly greater than that of the former but much less than that of check strains from severe streptococci infections. Studies of the application of the fibrinolytic test to the diagnosis of scarlet fever, to the examination of contacts and to the examination of patients for quarantine release in the limited number of cases available have yielded sufficiently significant results to warrant investigation on a larger scale.

Malignant Tumors of Nasopharynx—Needles presents a study of thirty-five cases of malignant tumors of the nasopharynx, sixteen of which manifested neurologic complications. Patients with disturbances of the auditory mechanism—whether tinnitus, deafness, pain or stuffiness in the region of the ear—should be subjected in a routine manner to a nasopharyngeal examination. Likewise, in the presence of enlargement of the cervical lymph nodes the possibility of a nasopharyngeal growth should be entertained as regularly as is tuberculous adenitis, the leukemias or Hodgkin's disease. For the neurologist, the presence of a basilar syndrome, especially with involvement of the cranial nerves coursing through the middle fossa, should immediately lead to the request for a nasopharyngeal examination. A basilar meningioma, a metastatic neoplasm, an inflammatory process or an aneurysm at the base of the brain can produce an identical neurologic picture, the differential diagnosis may therefore hinge on this simple diagnostic procedure. When, finally, in addition to the auditory symptoms there is enlargement of the cervical glands and involvement of the cranial nerves at the base of the brain, an irrevocable syndrome of nasopharyngeal malignant tumor is present. The results obtained from radiotherapy in cases of nasopharyngeal tumor are encouraging but as yet far from satisfactory. Earlier diagnosis and treatment may be the instrumental factor in correcting this defect. In cases which clinically present the picture of malignant tumor of the nasopharynx it is well to disregard a negative biopsy report and to proceed with appropriate radiotherapeutic measures.

Hormone Treatment of Cryptorchidism—Of the thirty-nine cases of cryptorchidism that Hess and Kunstadter treated with hypodermic injections of gonadotropic substance from the urine of pregnant women or from the placenta, complete descent

occurred in twenty-eight, partial descent in four and no descent in seven. The majority of the successful results followed a total dose ranging from 2,500 to 3,500 rat units. Those patients who were given more extensive courses of treatment had rest periods of from four to six weeks. The cryptorchid should receive a trial course of endocrine therapy before surgical intervention is resorted to. The resulting enlargement of the testes and their adjacent structures frequently lessens the difficulty of surgical procedures.

Grip as Seen in Pediatric Practice—Aldrich studied the data of 1,146 instances of grip, occurring in 845 different children during a period of six years. There were 222 second attacks, fifty-eight third attacks, fifteen fourth attacks, five fifth attacks and one sixth attack. He divides the symptoms and observations that led to the diagnosis of grip into three groups: those seen at the onset, those seen up to three days after onset and those seen subsequently. In the presence of an epidemic, the diagnosis is usually easy. However, one must be on guard continuously against jumping at conclusions and must rule out other respiratory infections by careful physical examination. The incubation period is about one week. During periods in which there is no epidemic, it may be necessary to make a diagnosis largely by exclusion. At such times family exposure often helps the clinician. The diagnosis is often corroborated when the patient transmits the disease to other members of the family. Laryngitis or croup occurred in smaller epidemics identical in time with those of grip, making it seem probable that croup is a manifestation of grip in infancy. The epidemics of grip showed no chronological relation to the prevalence of general respiratory disease as shown by comparison with the incidence of pharyngitis. Of the complications, otitis media and capillary bronchitis were by far the most common. Of the children who developed capillary bronchitis, 70 per cent were known to be asthmatic and another 17 per cent were probably allergic. The prognosis was good. The only death was from meningitis, which resulted when measles complicated grip with mastoiditis.

Nutritional Value of Spinach and Tomatoes—Tisdall and his collaborators compared the nutritional value of spinach as prepared for consumption with that available in canned tomatoes. Cooked spinach and canned tomatoes are approximately of equal value as a source of iron for the prevention and cure of nutritional anemia in spite of the fact that the total iron content of cooked spinach is more than three times greater than that of canned tomatoes. Spinach, although it contains 0.19 per cent of calcium, an amount twenty times greater than that found in tomatoes, actually tends to produce a negative calcium balance. On the other hand, the retention of the calcium in cooked tomatoes is excellent. The vitamin A content of cooked spinach is approximately four times as great as that of canned tomatoes. The vitamin B₁ content of cooked spinach is approximately one-half that of cooked tomatoes. The vitamin C content of cooked spinach is less than one-fourth that of canned tomatoes. The vitamin D content of cooked spinach and canned tomatoes is negligible. Sufficient prominence has not been given to the nutritional value of canned tomatoes.

Addiction to Barbituric Acid Derivatives—Robinson discusses some of the ill effects of the derivatives of barbituric acid. The little experimental work that has been done on heavy doses shows definite changes in the brain. The barbiturates

fall into the group of addiction-producing drugs. This statement is corroborated by the report of four cases in which the barbiturates were habit forming in certain psychologic types. This addictive action is similar to that of alcohol. There is, of course, a strong psychogenic factor in this class of cases, but the psychogenic factors are important in all forms of addiction. It requires a certain personality pattern in order that addiction may develop. Excessive doses destroy cerebral tissue and produce extreme toxicity. Barbitals addicts will take excessive doses and the deterioration frequently seen in these cases is due to destruction of cerebral tissue, which is accumulative over a period of time to a great enough extent to interfere with the patient's efficiency. The development of tolerance, while not as marked with these drugs as with some other forms of addiction-producing drugs, nevertheless leads the barbitals addict on to taking larger and larger doses so that the patient is soon taking toxic doses, which not only produce the clinical evidence of toxicity but also produce pathologic changes in the brain. These acute changes probably are the cause of the neurologic symptoms seen in barbitals poisoning both fatal and nonfatal. Laymen will use barbitals as the addict to alcohol uses alcohol.

Menstrual Purpura—Smith encountered five patients each presenting symmetrical purpuric rashes of the lower extremities coincident with or apparently related to the menstrual periods. There are many reports on menstrual exanthems but he wishes to differentiate these manifestations from the bilateral almost symmetrical purpuric rash of the lower extremities which so clearly defines his series. The following points are to be considered in establishing the diagnosis of menstrual purpura: 1. A distinct intracutaneous hemorrhagic rash is present recurrent during or related to the menstrual periods usually more

or less bilateral and usually limited to the lower extremities. It does not disappear on pressure. 2 The rash is usually associated with a scanty menstrual flow. 3 There is a definite decrease in the number of platelets, averaging approximately 200,000 per cubic millimeter of blood, without any noticeable change in the bleeding and coagulation time. 4 Other blood analyses do not present noticeable variations from the normal. 5 There has been a predominant nervous element in every case. 6 There is no tendency to spontaneous bleeding from mucous membranes. The ages of these patients varied between 18 and 30 years. Treatment consists in (1) relieving the itching of the rash, (2) establishing a normal menstrual flow by supplemental therapy (based on hypofunction of the ovaries, by use of theelin and corpus luteum extract) and stimulation therapy (use of anterior pituitary gonad stimulating hormone), (3) overcoming the nervous phenomena by assuring the patient and all concerned of a good prognosis, (4) eradicating all foci of infection as soon as the condition of the patient permits and (5) assuring the general well being of the patient by proper sleep, freedom from worry and mental strain, proper digestion of wholesome food and overcoming constipation.

Incontinent Patients in Chronic Hospital—Langworthy and his associates studied twenty-one male patients, who were segregated in one ward for special care because of habitual vesical incontinence, in an attempt to arrive at some conclusion concerning the cause of the trouble in each case. The work was possible through urologic and neurologic cooperation. The prostate was palpated by rectal examination. A cystoscopic study was made when deemed desirable. Each patient was examined carefully from a neurologic point of view to determine as far as possible the anatomic injury to the central nervous system and all showed abnormalities pointing to injury of the central nervous system. The cases were divided into six groups (tabes spinal paraplegia due to syphilis, hemiplegia, diffuse cerebral damage, hemiplegia associated with signs of bilateral encephalic lesions and injury to the bilateral cortico-spinal tract) depending on the level of the damage in the brain and spinal cord. A considerable group of these individuals had

lesions which could be localized in the spinal cord, brain stem or internal capsule. In most cases the changes were bilateral. In the remainder there was diffuse cerebral damage with no changes in the striated muscle or in the reflexes which are considered characteristic of involvement of the cortico efferent pathways. In these patients the lesion must involve the highest correlation centers controlling vesical activity. A patient with changes in striated muscle characteristic of damage to the cortico efferent pathways bilaterally presented a fairly normal vesical reading. Abnormalities of the bladder may be produced by cerebral cortical lesions without abnormalities of striated muscle, and conversely the changes in striated muscle may be present without marked abnormalities in the graphic record. Even so, in all the cases showing changes of marked degree in the striated muscle, incontinence was present.

Caustic Action of Potassium Permanganate—Johnston reports a case in which death resulted from the caustic action of potassium permanganate in solid form, which caused necrosis of the tissues of the mouth and esophagus and finally erosion of the esophagus leading to a fatal hemorrhage. Severe tracheitis and bronchitis leading ultimately to bronchopneumonia, appeared also to have a part. Potassium permanganate although not usually regarded as a dangerous preparation, will cause severe damage to the tissues, and even death, when applied in concentrated form. In the only four fatal cases so far recorded it has been taken with suicidal intent.

Indications and Contraindications to Splenectomy—Upham reviews the work, on splenectomy, of Doan, Wiseman and Curtis in the clinic of the College of Medicine of the Ohio State University. There were thirty-one splenectomies, seventeen of which were for hemolytic icterus, without a single fatality although six patients were in acute crisis and two had less than 2 Gm of hemoglobin and appeared practically moribund when taken to the operating room. There also were four cases of Banti's disease, three of thrombopenic purpura, three of hypoplastic anemia and one each of lymphatic leukemia, polycythemia vera, myeloid leukemia and leukanemia. The conclusions drawn are: 1 The pathologic physiology of the spleen may be manifest through either or both of two mechanisms inhibitory and destructive—and may affect any or all of the circulating blood elements. 2 The spleen is the major pathologic agent in congenital hemolytic jaundice. 3 Splenectomy is indicated as a prophylactic measure against clinical exacerbations of excessive hemolytic activity in the chronic and subacute manifestations of the disease. 4 Splenectomy is the therapeutic procedure in acute hemoclastic crises. 5 The immediacy of the erythrocyte response following splenectomy in hemolytic jaundice is dramatic, occurring on the operating table. This autotransfusion removes the necessity for preoperative or postoperative transfusions. 6 Splenectomy is not contraindicated in properly selected cases of thrombopenic purpura in acute crisis, provided adequate preoperative blood transfusions are given. 7 In Banti's disease early splenectomy offers some hope of prolonging life. 8 In hypoplastic anemia theoretically splenectomy should be of value. 9 In lymphatic leukemia splenectomy may prolong life but cannot be considered curative. 10 The operation is contraindicated in myeloid leukemia and polycythemia vera.

 Unexpected Hyperthyroidism Postoperatively A L Lockwood Toronto—p 499
 Recurrent Hyperthyroidism N W Gillette Toledo Ohio—p 504

Study of Thyroid Disease—Patterson and his colleagues give results of experimental studies which they believe indicate that a large part of thyroid disease may be congenital, being due primarily to an iodine deficiency in the mother. The literature has been reviewed and work which gives evidence that this does occur has been included. The scope of their study of this problem was as follows: (1) The cholesterol content of the blood of a series of pregnant women and rabbits was determined at frequent intervals, (2) the cholesterol content of the blood of a number of human infants at birth and rabbit fetuses at term was also determined and (3) by experimental and clinical observations they attempted to correlate the relationship of maternal and fetal blood cholesterol to the activity and cytologic structure of the fetal thyroid. Blood cholesterol studies on pregnant rabbits revealed that rabbits, unlike human beings, develop a hypocholesteremia in the second and third trimesters of pregnancy. Total thyroidectomy in the nonpregnant rabbit produces a hypercholesteremia but in the pregnant rabbit it has no effect on the blood cholesterol. The blood cholesterol of fetuses of totally thyroidectomized rabbits was more than 100 per cent higher than that of fetuses of normal rabbits. The thyroids of fetuses of thyroidectomized rabbits were in a state of extreme hyperplasia, showing definite evidence of hyperactivity. The hypercholesteremia occurring in pregnant women was reduced to normal by a small daily dose of thyroid extract indicating that the hypercholesteremia of pregnancy is due to hypothyroidism. The single human fetus in contrast to the many fetuses of a thyroidectomized rabbit is unable to furnish sufficient thyroxine to combat maternal hypothyroidism, and therefore if maternal hypothyroidism exists before pregnancy it may become more marked during pregnancy, owing to the necessary increase in metabolism. When maternal hypothyroidism and hypercholesteremia exist, fetal hypothyroidism and hypercholesteremia are also present. There is little doubt that the human fetal thyroid reacts to fetal hypothyroidism by hyperactivity and hyperplasia just as does the rabbit fetal thyroid and that this hyperactivity during development leads to permanent thyroid damage. Histologically the human thyroid at birth is in a state of hyperactivity. All the pathologic types of thyroid disease have been produced in animals by varying the intake of iodine and the physiologic demands of thyroid tissue. The presence of fetal characteristics in the adult thyroid is due to a failure of maturation caused by the extreme hyperactivity and hyperplasia occurring during development. The occurrence of goiter in more women than men is due to the increased thyroid activity necessary in menstruation and pregnancy. The development of goiter in persons who have had an adequate iodine intake since birth is due to the presence of damage incurred by the thyroid before birth.

 *Tryptophan Reaction as an Aid to Early Diagnosis of Meningeal Tuberculosis H Baxter—p 663

Tryptophan Reaction in Meningeal Tuberculosis—Baxter used the tryptophan test as an aid in the diagnosis of forty-one cases of meningeal tuberculosis. The result is positive if, at the junction of the fluids, a delicate violet ring is formed, and is negative when no ring is observed or if the ring is brown. The result is termed pseudopositive in fluids that are purulent, xanthochromic or stained with blood. Lumbar puncture was performed in the forty-one cases and the fluids were centrifuged before the test was applied. As a result of the investigation the forty-one persons of varying ages and both sexes subsequently found to be suffering from meningeal tuberculosis were shown to react positively with the cerebrospinal fluid tryptophan test. For the purposes of control, thirty-two cases were used and their fluids tested. All save one were negative. All the patients with meningeal tuberculosis died. There is a definite interval of time between the demonstration of the positive tryptophan reaction and other confirmatory evidence. In some cases three punctures and laborious search under the microscope proved futile and only necropsy confirmed the diagnosis. The average duration of illness of the patients at the time of lumbar puncture when the tryptophan test was positive was eight days, and the average day of death proved to be the sixteenth day of illness. That the tryptophan test may be useful in an early stage of the illness is shown by the results of seven of the cases under review. These cases showed a terminal phase of meningeal infection. The history of onset of illness could be relied on, and the tryptophan tests proved positive in two cases on the second day of illness, in three on the third day and in two on the fourth day.

Acrocyanosis—Stern examined hundreds of cases of acrocyanosis, in many of which careful observations have been made over a period of years. Acrocyanosis is due to certain changes in the arterioles caused by continual cooling of the parts. The condition is not always permanent. To detect it in all cases, special methods have had to be used, revealing that it is more prevalent than has been thought. Acrocyanosis is a clinical entity that may affect the hands or feet or both. The mechanism of the reaction of normal skin to cooling by ice or ice water is shown to depend on an axon reflex. The etiology of acrocyanosis is frequent moderate cooling of the affected parts in conjunction with chilling of the body as a whole. The age limits are wide, most of the present patients were between 20 and 45 years of age. Its mechanism is a partial obstruction to the arterial blood supply of the skin of the affected parts. There is no evidence of venous obstruction. Anatomic changes in the arterioles can only be excluded by direct observation. The obstruction is shown to be due to an increase in the muscular tissue of the middle coat of the arterioles of the cutis vera and subcutaneous tissue of the affected parts. It is not a mere matter of arteriolar spasm. Fibrosis and edema also occur locally but are probably only secondary. There is no evidence of any pathologic changes in the blood, nervous system or endocrine glands. In severe cases recovery from attacks may occur only after days of warmth. Treatment to be of permanent value involves practically continuous warmth for months.

- *Microscopic Inquiry into Etiology of Dengue Sandfly and Yellow Fever A C Coles—p 209
- Pulmonary Lesions in Animals Produced by Virus of Lymphogranuloma Inguinale E von Harm and R Hartwell—p 214

Etiology of Dengue, Sandfly and Yellow Fever—Coles examined air-dried blood films from ten naturally infected patients suffering from severe dengue during the first, second and third day of the disease and from two volunteers who were inoculated with 0.3 cc of dried serum of infected blood, from yellow fever in monkeys and from three human cases of sandfly fever. Small free and intracorpuseular bodies were found in the blood of dengue, sandfly and yellow fever. The blood in these cases showed practically no evidence of anemia and the red blood corpuscles were in all cases regular in size, shape and staining reaction, and beyond the presence of a few punctate red cells in some of the films of blood from dengue fever not the slightest signs of pathologic red cells were found, and in no case was a single nucleated red corpuscle seen. The filtrable organisms in sandfly, dengue and yellow fever are quite different but probably closely allied. These intracorpuseular bodies agree in the following particulars: 1 They are easily stained by Giemsa and take about the same color. 2 All have much the same morphologic characters and show some internal structure consisting usually of more deeply stained dots or granules. 3 They are numerous in the blood in cases of dengue and yellow fever during the first three days and in

sandfly fever during the first twenty-four hours. 4 They all show evidence of undergoing developmental stages. The bodies found in dengue fever are on the whole the smallest, those in yellow fever are intermediate in size, while those in sandfly fever show considerably greater variations in size and contain many larger forms than the other diseases. The fact that the bodies in the corpuscles and in the plasma of dengue, sandfly and yellow fever are to be found only during what is known to be the most infective period, that they are then present in such enormous numbers and that, in the case at least of dengue, they diminish and disappear in a very short time suggests that they are definitely associated with and are probably the actual causal virus of these diseases.

Ephedrine in Treatment of Enuresis—Brookfield administered ephedrine in thirty-eight consecutive cases of enuresis over periods up to several months. The enuresis ceased in ten cases, and there was improvement in fourteen others. The ephedrine sometimes caused restlessness and other side effects, but these were seldom seen in older children of phlegmatic type, some of whom seemed to have an unusual tolerance to the drug. Those cases in which enuresis persists throughout school life only to cease in the late teens or early twenties are the ones in which ephedrine appears to be of most value. To such sufferers in particular ephedrine offers a prospect of permanent cure, and it is worthy of trial in the majority of younger subjects, many of whom will be similarly benefited. In adopting the method the presence of a urinary infection is excluded by examination of the urinary deposit. Half a grain (0.032 Gm) of ephedrine alkaloid in tablet form is given at bedtime. The dose is increased by half a grain every three to four nights until in certain instances as much as 5 grains (0.32 Gm) is taken. In those cases which respond favorably it is found that enuresis at first becomes less frequent and then, as the dose is increased, disappears altogether. The fact that many sufferers from enuresis are able to tolerate doses of ephedrine considerably in excess of those usually regarded as maximal lends support to the view that enuresis is sometimes a manifestation of a constitutional type, in which the parasympathetic-sympathetic balance is weighted in favor of the parasympathetic system. In this way considerable enhancement of sympathetic activity is required before the hypertonic parasympathetic can be opposed adequately. Thus a relatively large amount of ephedrine is utilized and there is no excess to give rise to unwelcome side effects.

*Comparative Capillaroscopic Picture of Primary Manifestation of Syphilis and of Soft Chancre N W Nicolas and Mme T N Liberman—p 700

Capillaroscopy of Venereal Lesions—Nicolas and Liberman point out that capillaroscopy is a valuable complementary method for clinical investigation not only in internal medicine but also in dermatology. Following a brief review of the literature on capillaroscopy in dermatologic disorders they describe their own capillaroscopic investigations on soft chancre and the lesion of primary syphilis and present the most characteristic aspects of the two processes. The circumference of the syphilitic lesion presents a faded tinge, whereas that of soft chancre has vivid colors. In the skin surrounding the syphilitic region the capillary loops have a tendency to be vertical, whereas in soft chancre they are horizontal, their summits being directed toward the center of the ulcer. The outline of the syphilitic lesion is clear cut and gives the impression of a deep furrow, but in soft chancre it is indicated by a radius of a whitish rose color. The fundus of the syphilitic lesion is reddish, but the bed of the soft chancre is yellowish brown. In the syphilitic ulcer hemorrhages are frequent, whereas in the soft chancre they are not. The authors admit that further studies will be necessary to perfect the technic, but they think that in some cases it can serve as a complementary method for the diagnosis of venereal disorders. The method has the disadvantage that it cannot be used in all localizations and that it cannot be employed in women.

*Electrocardiographic Aspects of Angina Pectoris R Froment and A Vachon—p 531

Electrocardiographic Aspects of Angina Pectoris—Froment and Vachon made electrocardiographic studies on thirty-one patients with angina pectoris which confirmed the frequency of the negativity of the T wave of the ventricular complex in leads 1 and 2 during the attack. The comparison of the electrocardiogram and of clinical and roentgenologic aspects in each of these thirty-one patients permits the following conclusions: 1 The electrocardiographic changes and especially the isolated negatization of the T wave in leads 1 and 2 as a rule exist in the anginous syndrome which anamnesis and examination permit attributing to coronary arteritis. 2 These electrocardiographic changes are the exception in the types of angina the coronary origin of which appears clinically doubtful (only one case with negative T wave in nine cases of this type), cases of evident "neurotic" pseudo anginous pains being excluded. 3 In patients with syphilitic aortitis with angina these changes likewise have been observed rarely. The authors show that the electrocardiographic aspects of angina pectoris are important for the diagnosis. The electrocardiographic record may indicate the organic character of the pain and may permit the affirmation of its coronary origin. In the cases in which the etiology remains doubtful, it may point to a coronary arteritis. Regarding the prognostic significance of electrocardiography in angina pectoris the authors say that it is derived from the notion of coronaritis and from the importance of the greater or lesser qualitative modifications of the cardiac contraction. It gives the possibility of determining the evolutionary or stable character of the electrical changes and thus of the coronary disorders.

Presse Medicale, Paris

Cancer of Breast with Skeletal Generalization Treated with Tele-roentgen Therapy F Trumoheres and L Mallet—p 1433

*Metabolism of Amino Acids in Gastroduodenal Ulcers K Herriot—p 146

Metabolism of Amino Acids and Gastroduodenal Ulcer—Herriot points out that Aron and Weiss introduced amino acids especially histidine into the treatment of gastric and duodenal ulcers and then he describes his own experiences in 160 cases of gastric and duodenal ulcers in which he resorted to histidine treatment. The favorable therapeutic results

obtained in these cases induced him to study the metabolism of the amino acids in patients with gastric and duodenal ulcers. The mode of action of histidine has been given various interpretations. Aron and Weiss suggested that the ulcerous lesions result in a disturbance of the metabolism, the cause of which must be searched for in a deficiency of the amino acids. Other authors, however, ascribed the action of histidine chiefly to its analgesic effect. The theory of Weiss and Aron raised the question of the clinical significance of the amino acids. In the intestine the albumins are decomposed into amino acids and the blood stream continually contains such acids. The author determined the amino acid content in the venous blood and studied the reaction produced by the intravenous injection of amino acids. He made these tests with the method of Fohn and with the modification suggested by Horejsi and Mecl. He observed neither augmentation nor diminution of the free amino acids in the venous blood of 100 patients and he was unable to detect a difference in patients with gastric and duodenal localization of the ulcer, although the therapeutic effect of the histidine was usually more rapid in cases of gastric ulcer. In studying the reaction produced by the intravenous injection of amino acids, he found that in the patients who were given histidine the blood tests revealed curves which were similar to those which Bufano had observed in normal persons. Patients who were given a solution of histidine monochlorohydrate showed, fifteen, thirty, sixty and 120 minutes after the administration the same values as before. Thus the patients with gastric and duodenal ulcers react in the same manner as do persons without such disorders. In the conclusion the author points out that, although he was able to verify the favorable therapeutic effects of histidine in gastric and duodenal ulcers, he was not able to corroborate Aron's theory of the mode of action. He is of the opinion that the sedative action rather than the effect on the amino acids is the important factor. He thinks that the sedative action of the histidine is borne out also by the rapid disappearance of the pains after the administration of small doses and the favorable therapeutic results obtained in gastritis and in nonulcerous gastric disorders.

Prophylaxis and Therapy of Whooping Cough with Vaccine A Hottinger—p 947

*Acute Peritoneal Syndrome as Hypersensitivity Reaction Problem of Acute Serous Peritonitis E Melchior—p 950

Treatment of Alcoholic Addicts and Psychiatric Policlinics J Wyrsch—p 951

Acute Peritoneal Syndrome as Hypersensitivity Reaction—Melchior reports a case which demonstrates that acute serous peritonitis may be the dominating partial manifestation of a general vasomotor reaction of hypersensitivity. A man aged 22, suddenly developed from unknown causes, severe symptoms indicative of an acute perforation of the stomach, which might have been taken as an indication for an immediate laparotomy. That such an intervention would have been superfluous is proved by the fact that the abdominal signs subsided almost as rapidly as they had appeared. Certain accompanying symptoms throw light on this process. It was found that a severe dermatographism existed during the acute abdominal phase. Moreover, infusion of physiologic solution of sodium chloride into the subcutaneous connective tissue produced a hypersensitivity reaction, presenting the aspects of an acute phlegmon. On the basis of these observations the author assumes that the peritoneal symptoms were the manifestation of a serous peritonitis which was a part of the same reaction that elicited the severe dermatographism and the pseudophlegmon. An alimentary noxa was presumably the causal factor. The character of the abdominal symptoms—the sudden onset of the pains their uniform persistence and their spreading over the entire abdomen—mitigates against the existence of simple intestinal spasms and indicates an inflammatory involvement of the peritoneum. The author points out that this interpretation is not entirely new and directs attention to analogous conditions such as the serous ascariasis peritonitis, which he regards as a reaction to the toxic products of these enterozoa. Further he suggests that the frequent serous exudates of acute appendicitis may be a hypersensitivity reaction to bacterial toxins and that visceral symptoms accompanying attacks of urticaria may find their explanation in this manner.

Bactericidal Power of Blood—The experiments of Bacchini and Marzocca showed that the whole blood of dogs and rabbits has bactericidal power on staphylococci and colon bacilli before splenectomy. It loses its power immediately after splenectomy but regains it between the tenth and thirtieth days. It becomes normal again after thirty days. According to the authors anesthesia plays no part in the changes of the bactericidal power. The spleen is not indispensable for the production of the phenomenon. Splenectomy is followed by a reaction of the reticulo endothelial system which results in hypertrophy of the lymph nodes in the mesentery and in certain tissues in the peritoneal cavity. The hypertrophic lymph nodes take on a structure similar to that of the spleen and they develop vicariously the functions of the spleen with consequent restoration of the bactericidal power of the blood.

*Sulfanilamide (Prontosi) in Treatment of Erysipelas E Marzollo—p 340
Fatal Spontaneous Subarachnoidal Hemorrhages in Young Persons Cases M Venezoni—p 368

Sulfanilamide in Treatment of Erysipelas—Marzollo administered sulfanilamide to twenty-six patients who were suffering from acute erysipelas. The group included infants, children and adults of both sexes. Tablets of 0.3 Gm of sulfanilamide each were administered. Infants were given half a tablet, children and adults one tablet, and in rare cases adults were given two tablets at a time. The tablets were dissolved in a spoonful of water and administered by mouth two or three times a day shortly after ingestion of milk or broth. The treatment was administered for three or six days. In rare cases the disease was controlled by administration of the drug for only one day or it was necessary to give it for as long as seven or eight days. In the latter case the dose was cut to half of that which was administered for the first three days. In all cases the treatment was associated with local applications of 10 per cent ichthammolated petrolatum. The treatment is well tolerated. Fever abates and leukocytosis diminishes during the first or second day of the treatment or, in rare cases, during the third or fourth day. As a rule, fever disappears by crisis (88 per cent in the cases of the author). The cutaneous symptoms improve as soon as fever abates. The author compared the results obtained from administration of sulfanilamide with those obtained in a group of forty patients suffering also from acute erysipelas and treated by vaccines, nucleoproteins or colloidal silver. The disease follows a more even and uncomplicated evolution and the duration of fever and of the disease is shorter in patients treated with sulfanilamide than in those who are given other treatments. The author considers sulfanilamide the treatment of choice in erysipelas, especially in infants.

*Intensification of Cutaneous and Visceral Allergy from Histamine Injection F Corelli—p 491
Action of Anterior Hypophyseal Extract (Lipotrina) on Metabolism of Carbohydrates C Borruo—p 501
Attempts to Induce Appearance of Spirochetes in Blood of Patients Suffering from Relapsing Fever D Sibilia—p 530

Intensification of Visceral and Cutaneous Allergy—Corelli administered a subcutaneous injection of 0.8 or 1 mg of a solution of histamine to several patients presenting cutaneous or visceral diseases of an allergic origin. In fourteen cases of erythema nodosum, of tuberculous or rheumatic fever etiology, the histamine injection was followed by intensification

of the preexisting erythematous lesions and appearance of new lesions. The reaction takes place shortly after the injection and lasts for thirty or forty minutes. It develops also in the skin of patients who are suffering from urticaria, Quincke's edema, serum disease, exudative erythema and certain exanthematous diseases of children and adults. The subcutaneous injection of histamine causes intensification of skin and intradermal positive tuberculin and other reactions and a transient aggravation of lesions of pulmonary tuberculosis. It induces an increase of bilirubinemia and of provoked glycemia in catarrhal jaundice and of albuminuria and azotemia in acute diffuse glomerulonephritis. The author points out the possible value of the reaction in the clinical and differential diagnosis of allergic diseases. He discusses the mechanism of production of the reaction, which, according to him, is due to a nonspecific dilating action of histamine on the permeability of the capillaries of inflamed tissues.

Prensa Medica Argentina, Buenos Aires

Pleurisy and Granuloma in Primary Infection O Garre—p 1836
Physical Bases of Roentgen Therapy C H Niseggi—p 1839

Influence of Lateral Position on Rest of Lung—Vaccarezza and his collaborators studied the influence of lateral positions on rest of the lung in twelve normal adults, of both sexes, by means of thoracometry and x-ray examination of the thorax. They found that the volume of the lung in the side on which the patient lies is smaller, both during inspiration and expiration, than it is when the position is changed to the opposite side. It is smaller also than it is when the person lies in the dorsal position. The difference between the volume of the lung in inspiration and in expiration is greater for the lung in the lower than in the upper position and smaller for the lung in the lower position than it is when the patient lies on his back. However, the difference takes place within volumetric figures which are smaller for the lower lung in comparison to those of the lung in the upper position or when the patient lies on his back. The lower lung is in a condition of elastic hypotension by which the organ is at greater rest in the lower than in the upper and dorsal positions.

Xanthomatous Inflammation in Surgical Diseases—Biehl presents a study of fifteen cases of secondary xanthomatous alterations observed in most varied surgical diseases such as pyonephrosis, renal tuberculosis, chronic cholecystitis, simple chronic mastitis, perinephritis, subphrenic abscess, osteitis fibrosa, synovitis of the knee joint, chronic osteomyelitis, brain abscess and endothelial sarcoma. The cause of the so called xanthomatous giant cell tumors is to be seen in external trauma or in a hypothetic metabolic trauma. It is assumed that there is a disturbance of the lipid or cholesterol metabolism. Frequently it is of a local character. The giant cells of these xanthomatous granulomas are to be regarded as a special variety of foreign body giant cells which originate from the fixed connective tissue as well as from the reticulo-endothelial system. The so called foam cells or xanthoma cells which give these pseudotumors their particular appearance, develop exclusively from the reticulo endothelial cells. These cells point to a local metabolic disturbance. Certain xanthomatous giant cell tumors are too highly differentiated to be considered benign tumors. Newer studies of the giant cell tumors in osteitis fibrosa contain hints regarding the

nature of such blastomas. According to Puhl, the localized brown tumors, cysts and giant cell tumors of the bone marrow are benign mesenchymal tumors of nondevelopmental origin. In the author's opinion this should hold true for similar tumors of tendon sheaths, joints and so on. These tumors, however, differ from all others by the alteration of their metabolic activity, particularly that concerned with the lipid metabolism. The author demonstrated that not only the foam cells but also the ordinary tumor cells contain an unusual amount of lipoids. Because of this predisposition on the part of these tumor cells to abnormal metabolism in a general sense and to the lipid metabolism in particular, the author proposes a generic name of "metabolic blastoma" for all such tumors, with a specific designation of "metabolic xanthoblastoma." Hypercholesterolemia is not a necessary condition, since the tumor cells themselves are capable of increasing the local lipid content. The hemosiderin deposits in the stroma of these tumors are caused by hemorrhages from small vessels resulting from a toxic effect.

Gastroduodenal Ulceration in Japan—In Japan, according to Tomoda, 378 cases of gastric ulceration were found in 8,099 necropsies, or 4.66 per cent, and thirty-two cases of duodenal ulcer in 6,120 necropsies. In Europe and in America gastric ulcer occurs with greater frequency in women, while in Japan both gastric and duodenal ulcers occur with much greater frequency in men than in women. Their operative mortality with gastro-enterostomy amounted to 5.2 per cent and the proportion of radical cures to 80 per cent. There was only one instance of a peptic jejunal ulcer. Among thirty-three patients on whom operation for exclusion was performed, there was one operative death. Complete cure was found in 100 per cent of the twenty-three cases followed up. Of 135 patients subjected to partial gastric resection, twelve died (8.7 per cent) and seventy-five of eighty-three followed up (90.36 per cent) were cured. There was one case of peptic jejunal ulcer. Multiple ulcers were demonstrated in 4.8 per cent of the gastro-enterostomies and in 26.4 per cent of the gastric resections. This suggests the ease with which multiple ulcers may be overlooked in the course of a gastro-enterostomy. The results after gastro-enterostomy, operation for exclusion, or partial gastric resection do not depend on the alteration of the gastric resection. The frequency of malignant degeneration of the gastric ulcer amounted in their material to 6.5 per cent, while in the patients subjected to partial gastric resection as a separate group it was 16.1 per cent. As a result of experience during the last sixteen years the author considers partial gastric resection the best method. Operation for exclusion is preferable to gastro-enterostomy for duodenal ulcers that cannot be resected. Gastro-enterostomy is to be reserved for ulcers located in the pylorus or its vicinity, particularly when complicated by stenosis.

Surgery in Fractures of Base of Skull—Fehr and Meier present an analysis of the results of conservative treatment of the fractures of the base of the skull. In seventeen years (from 1919 to 1935), 417 patients with fracture of the base of the skull were admitted to the university clinic of Zurich. The conservative treatment consisted of rest in bed for from three to four weeks, application of an icebag and administration of methenamine. The lumbar puncture for diagnostic purposes as well as to influence the rising intracranial pressure was widely employed. With the exception of a single case of meningitis which developed following the lumbar puncture and was associated with a sudden closure of the aqueduct of Sylvius there were no untoward symptoms observed as the result of the procedure. The authors likewise observed good results from

intravenous administration of hypertonic solution of dextrose. As a rule, from 40 to 100 cc of a 20 to 40 per cent solution frequently with the addition of methenamine, was administered daily. The total mortality amounted to 32.4 per cent. Among 383 cases in which conservative treatment was resorted to there was a mortality rate of 28.3 per cent. Thirty-two patients were submitted to operative intervention, with a mortality rate of 81 per cent. The treatment of basal fractures, in the opinion of the authors, is the domain of the surgeon in cooperation, however, with the neurologist and the eye and ear specialist. The treatment is essentially conservative, there being no primary indications for surgical intervention. A prophylactic intervention for fractures of the anterior or the middle fossa is not to be recommended in view of the fact that prevention of an intracranial inflammatory complication is a matter of uncertainty. In fractures of the anterior fossa an operation is indicated if there is danger of a spreading infection from a demonstrated infection of the nasal cavities. In fractures of the middle fossa it is of great importance to ascertain whether one deals with a longitudinal or with a transverse fracture of the petrous portion of the temporal bone. Recovery without complications takes place as a rule in the longitudinal fractures even when complicated by middle ear infection or by leakage of the cerebrospinal fluid. In transverse fractures associated with an opening into the inner ear, there is grave danger of meningitis. Operative intervention is indicated in fractures of the middle fossa when complicated by middle ear infection or in the presence of a beginning meningitis. Among the late complications there were abscesses of nasal origin as well as late abscesses after longitudinal fractures of the petrous portion. Both complications occur seldom and both are amenable to successful operative treatment. Late meningitis is a more frequent occurrence following transverse fractures of the petrous bone. Patients with a fracture of the labyrinth require, therefore, continued otologic observation for possible complications.

Mesenteric Lymphadenitis—In an extensive review of the subject of mesenteric lymphadenitis, Hertel asserts that non-specific inflammation may involve the mesenteric lymph nodes as well as those of any other region. Infections and toxic substances reach these nodes by way of the lymphatic channels as a rule from the intestine or from the appendix, frequently in the presence of a sore throat and exceptionally by way of the blood vessels. The responsible local structure, such as the appendix, for example, is frequently not involved. The infection may begin as a primary lymphangitis. Acute, subacute or chronic lymph node infection may give rise to considerable peritoneal manifestations. While the lymph node infection is secondary, clinically it may dominate the picture. The term mesenteric lymphadenitis is justified in the opinion of the author. The diagnosis is difficult but possible in occasional instances. Obscure abdominal symptoms are not infrequently the result of nonspecific disease of the mesenteric lymph nodes. The removal of the appendix and, in certain cases, the removal of the infected lymph nodes of the ileocecal angle are indicated. In cases preceded by angina, tonsillectomy is indicated.

Survival of Spirochetes in Fluid Nitrogen—In a preliminary experiment Jahnke determined that the spirochetes of recurrent fever as well as the trypanosomes of dourine survive after having been placed for twenty minutes in fluid nitrogen that is after having been exposed to a temperature of minus 196 C (—320 F). The main experiment consisted in exposing to the influence of fluid nitrogen for two weeks spleen

and liver of mice which had been infected with recurrent fever, dourine or rat bite fever, as well as pieces of syphiloma from rabbits. After the organs were thawed again, inoculation experiments still produced positive results in the case of the different spirochetes (recurrent fever, rat-bite fever and syphilis) but the trypanosomes proved no longer infectious. It is noteworthy that the spirochetes not only tolerate prolonged storage at minus 196 C but also that they tolerate the sudden reduction from room temperature to the temperature of fluid nitrogen, that is, a drop of 220 degrees C (396 F) and again the sudden increase of temperature by the same number of degrees. The author conducted these and other experiments in order to detect a simple procedure for the conservation of spirochetes and trypanosomes. Although he did not realize this aim, his experiments proved the great resistance of spirochetes to extremely low temperatures.

Significance of Coproporphyrin—Beckermann and Schulke demonstrate that coproporphyrin is a comparatively frequent constituent of feces. Its presence in the human intestine proves only that autogenous or heterogenous blood pigment has reached the intestine. To conclude from its presence its origin in autogenous blood, blood pigment or hematin is permissible only if the food has been free from heterogenous blood or hematin. Moreover, even if the autogenous origin of the coproporphyrin has been proved, it cannot be determined whether the blood originated from a benign or malignant lesion of the mucosa, so that a positive coproporphyrin test does not indicate whether ulcer or carcinoma exists. However, the authors show that the examination for the presence of coproporphyrin is too complicated to deserve consideration as an auxiliary method of examination.

Phagedenic Ulcer on Basis of Cutaneous Diabetes—Urbach reports the history of a man, aged 53, who developed a phagedenic ulcer on the chest. About three weeks before hospitalization the patient had first noted a red area over the distal part of the sternum. Later there developed slight secretion and scab formation. Conservative treatment was begun at this time, but it did not arrest the progressive ulceration. Polydipsia and polyuria were overlooked, but since a brother and sister of the patient had diabetes the blood sugar content was determined and revealed a mild increase. However, a sugar tolerance test revealed severe diabetes. In view of the phagedenic character of the ulceration a cutaneous diabetes was thought of. This condition is characterized by cutaneous disorders (furuncles, ulcerations, eczemas, pruritus, abscesses of the sweat glands) that are refractory to treatment, by high sugar content of the skin but normal sugar content of the blood, while the patient is fasting, and by the fact that the cutaneous disorder is favorably influenced by restriction of the carbohydrate intake combined with insulin therapy. In the reported case the ulceration proved refractory to all measures until an antidiabetic diet and insulin therapy was instituted. Under the influence of the latter measures, further spreading of the ulcer was arrested and it was finally cured. The author says that the phagedenic ulcer resembled gangrene but could be differentiated from this condition by the complete absence of a bacterial flora, by the demonstration of the diabetic disturbance and by the efficacy of the antidiabetic treatment.

Relations Between Metabolism and Migraine—Franck reports observations on eight patients with migraine who were carefully observed and frequently examined. It was found that six of them had a hereditary history of migraine. Hepatic and biliary disturbances were observed in five cases. The func-

tion of the pancreas was investigated in four of the patients, and three of these proved to have a hypofunction of the pancreas. Retention of water was observed in five of the patients. In all patients an increase in the urobilin bodies of the urine was observed during the attack of migraine. The regularity of the increase in the urinary urobilin is regarded as an indication of a disturbance in the intermediary metabolism of the liver. The author suggests the following development of an attack of migraine: the autointoxication originating in the liver impairs especially the brain. A cerebral edema results. Moreover, disturbances in the cerebral blood perfusion which, judging by the attack-like development of migraine, doubtlessly play a part in migraine, likewise can be explained as resulting from hepatic autointoxication. To be sure, the author does not want to imply that migraine is always caused by a hepatic disorder, for, as already indicated, other factors, such as heredity, seem to play a part.

Viscosity of Blood Serum in Hepatic Disorders—Kaunitz and Kent investigated the relative viscosity of the blood serum in 152 persons without hepatic disorders and in ninety-five patients with icterus and compared it with the total protein content of the serum and with the albumin/globulin quotient. The aim was to determine whether changes in viscosity that are not caused by quantitative deviations in the serum protein fractions occur in patients with hepatic disturbances. In the "normal" cases it was found that among the patients with high protein values, there is a higher percentage of low albumin/globulin quotients than among those with low protein values. This surprising fact does not apply to serums of patients with nephritis and with hepatic disease, in the majority of whom the albumin/globulin quotient is low. The relative viscosity of the serum was nearly always greatly increased in cases of cavernous phthisis and extrapulmonary tuberculosis, whereas the values were generally normal in the benign, fibrous forms of tuberculosis. The increase in the relative viscosity was especially pronounced in patients with hepatic cirrhosis. In catarrhal icterus and in disorders in which the icterus was due to mechanical obstruction, the cases with an especially severe impairment of the hepatic parenchyma showed a noticeable increase in the relative viscosity. In the course of studies on the relations between the Takata test, the albumin/globulin quotient and the relative viscosity, it was found that, in one third of the cases showing a positive Takata test, the albumin/globulin quotient is above 1, that is, in a large number of these cases the positivity cannot be caused by a relative increase in globulin. A great increase in the relative viscosity of the serum was observed in twenty-six of forty-one cases. The authors point out that this, in connection with some of their earlier observations, supports the opinion that for the development of a positive Takata reaction it is necessary that the serum protein bodies undergo also qualitative changes. Another observation in the course of the Takata reaction was that it was positive not only in hepatic cirrhosis but also in many cases of the severe forms of tuberculosis. The authors reach the conclusion that many deviations from the normal serologic reactions which occur in hepatic diseases are caused by the "pathologic" protein bodies that are demonstrable in these diseases.

Testing of Respiratory Function by Means of Histamine Tolerance Test—Schlosser says that a good test for the respiratory function should provide information about the lung as the organ of diffusion for respiratory gases. He discusses the method of Heymer. After the values for pulse, blood pressure, vital capacity and respiratory pause have been determined, the subject is given a subcutaneous injection of 1 cc of a preparation which contains 1 mg of histamine. Ten,

twenty and thirty minutes after the injection the values for pulse, blood pressure, vital capacity and respiratory pause are determined again. Heymer found that in healthy persons the injection of histamine neither shortens the respiratory pause nor reduces the vital capacity, that is, healthy persons have sufficient respiratory and circulatory reserves to compensate for the impairment by histamine. In patients with pulmonary and circulatory disorders, however, the injection of histamine always results in a reduction of the vital capacity and in a shortening of the respiratory pause. The author employed Heymer's histamine method for testing the respiratory function of 188 men in a sanatorium for tuberculous patients. This material included all forms of tuberculosis. He found that the test is a valuable aid in determining the advisability of collapse therapy and in testing the working capacity of a tuberculous patient. It has the advantage that it requires no special apparatus. All that is needed is a spirometer, a stop watch and a blood pressure apparatus. The only slight disadvantage is that it cannot be employed without the cooperation of the patient.

Tuberculosis of Breast—Sallie Hoben—p. 767

Action of Hormone of Hypophysis on Vasomotor Center—Seligsohn's experimental research was made on dogs anesthetized with paraldehyde by way of the stomach in doses from 125 to 135 Gm per kilogram of body weight, or with urethane by intracutaneous injections of 18 Gm per kilogram of body weight. He selected those two narcotics on account of their action on the cortex of the brain. He concludes from his experiments that 1. Pure "vasopressin" dissolved in physiologic solution of sodium chloride and administered suboccipitally in doses of 10 units causes a high blood pressure. 2. Preparations of hormones of the anterior hypophysis, and especially of the corticotropic and adrenotropic hormones introduced suboccipitally in the same amounts, do not influence the blood pressure. 3. All hypotonic solutions given suboccipitally cause a temporary decrease of the blood pressure, not always followed by increase of blood pressure. Diluted hypotonic solutions and distilled water cause a sudden, deep drop of the blood pressure, accompanied by arrest of the heart action for a few seconds and followed by weak pulse caused by irritation of the center of the vagus nerve in the medulla oblongata. 4. Slightly hypertonic solutions do not cause any action on the blood pressure but act as an irritant on the respiratory center. More saturated solutions act similarly to distilled water. 5. All solutions administered to human beings for diagnostic or therapeutic purposes must be strictly isotonic in order to avoid the complications caused by hypotonic solutions. 6. Through suboccipital or lumbar injections it is possible to exert a direct action on the vasomotor, the vagus nerve and the respiratory centers, which can have a practical value in cases of shock to these centers, as for example in cases of accident by lightning or electric current.

X-ray Information Supplied by Splenic Puncture in Diseases of Spleen and Blood—P. Enlie Weil, P. I. Ch. Wall and S. Perle—p. 84

Treatment of Thyrotoxicosis—Meyler discusses three points. 1. The unfavorable effects of intercurrent infections in thyrotoxicosis. He observed five fatalities from mild angina in patients with thyrotoxicosis and cites the case of a woman who died of a mild exanthema after she had been prepared for a goiter operation. He also describes animal experiments which

prove the lowered resistance to intercurrent infections during thyrotoxicosis. 2. The hepatic function in thyrotoxicosis. The hepatic function is impaired in most patients with exophthalmic goiter. This is demonstrated by the urobilinuria and the reduced galactose tolerance of these patients. The treatment should aim at an improvement in the hepatic function by providing a diet that is rich in carbohydrates and vitamins and by administering insulin. However, there is no advantage in an abundant diet. 3. The value of a hunger diet in thyrotoxicosis. He points out that a hunger diet has been shown to depress thyroid function in normal people. This treatment was therefore tried in sixteen cases of exophthalmic goiter. Excellent results were obtained with diets of from 800 to 1,000 calories a day containing only 20 Gm of protein. The effect was permanent in only three of the cases. In the other cases an increase in the diet was followed by a new rise of the basal metabolism. Nitrogen balances and creatine excretion were studied during the dietary treatment. The author finally discusses the physiologic basis of this type of therapy.

Treatment of Adiposogenital Dystrophy—Plum reports his experiences with the intramuscular injection of a gonadotropic hormone preparation in five cases of adiposogenital dystrophy, in two cases of cryptorchidism and in one case of adiposity. The preparation that he employed was extracted from pregnancy urine, it is said to be free from the estrogenic principle and it is standardized on the basis of its luteinizing effect on mice. In adiposogenital dystrophy the treatment with gonadotropic substance alone produced in from six to eight weeks a marked growth of the genitalia but no change in the metabolism or in the distribution of fat. By combining this treatment with thyroid therapy, a marked loss in weight was obtained. In one patient with cryptorchidism but without signs of endocrine disturbances the treatment was followed by a marked growth of the genitalia, but the testicles did not descend in the course of two months' treatment. In another patient with cryptorchidism, combined with adiposity and decreased metabolism, descent of the testicles was obtained in two weeks. In a few instances the treatment caused a little tenderness at the site of injection, otherwise there were no untoward effects of any kind.

Blood Picture and Sedimentation Reaction After Pneumothorax—Mourier tabulates the results of thirty-three examinations in twenty-eight patients, made partly before insufflation, partly one-quarter hour, one, two and three hours after insufflation. Even a quarter hour after insufflation he found changes in the percental composition of the blood, consisting of (1) from 3 to 14 per cent increase in neutrophil elements in most cases, in some about 25 per cent increase, (2) from 4 to 15 per cent decrease in the lymphocyte count, in some cases up to about 20 per cent decrease, (3) 8 or 9 per cent increase in the monocyte count after a transient fall of 3 or 4 per cent and (4) in some cases a 2 or 3 per cent further shifting to the left in the Arnetti picture. The absolute leukocyte count per cubic centimeter showed an increase of up to 14,000, in most cases varying from 4,000 to 8,000. The sedimentation reaction was usually unchanged, the reduced sedimentation after insufflation mentioned by Lotze and Pongor was not seen. The author says that the changes are about the same, whether the insufflation is unilateral or bilateral, they are apparently independent of the degree of completeness of the pneumothorax and in most cases are independent of whether the final pleural pressure is positive or negative. The results agree with Mazzetti, Geronimo and Gestaldi's "hemoclastic curve," except that no decrease was established in the absolute leukocyte count but on the contrary, an increase. The reaction must depend on a reaction of the collapsed lung, whether it is due to spread of smaller amounts of tuberculin (Mazzetti, Geronimo and Gestaldi) or to a change in the pulmonary circulation is not known.

PRESENT CONCEPTS OF ACUTE CORONARY OCCLUSION

CLINICAL LECTURE AT ATLANTIC CITY SESSION

CHARLES C WOLFERTH, M.D.

PHILADELPHIA

The terms coronary occlusion, coronary thrombosis and cardiac or myocardial infarction are often employed as synonyms, although there are useful differences in their meanings. Coronary thrombosis refers to a special type of coronary occlusion in which thrombosis is the final event in the process of occlusion. Myocardial infarction, although a frequent result of acute coronary occlusion, does not always follow it.

FREQUENCY

One of the much discussed questions of the day is whether coronary disease is becoming more frequent than it was in former years or whether it merely seems to be more frequent because some progress has been made in its recognition. All present day statistical studies reveal its importance as a cause of death. Most writers on the subject assume that its incidence is rapidly increasing. The further assumption is usually made that the increase is due to stress and strain of modern life. On the other hand, Cohn and Lingg¹ concluded from their statistical study that, if account is taken of changes in fashions in diagnosis, there has been a relatively small increase in the death rate from circulatory disease during the past thirty years and that recently the increase has been "ever slighter." Even the small increase seems to depend largely on the fall in the rate for infectious diseases in the very decades in which a rise for the circulatory group took place. They stated that belief in the theory that stress and strain of life account for increase in the death rate from cardiac diseases is unnecessary.

There appears to be considerable doubt as to the accuracy of statistics that are being collected even at the present time. Hedley² concluded from his study of hospital statistics that "it is not possible to obtain an accurate conception of the total number of deaths from heart disease or of any of the various etiologic types."

So far as any attempt to compare the present and the past incidence of acute coronary occlusion is concerned, physicians are almost entirely in the dark. Few persons in preceding generations even knew there was such

a malady. Parkinson³ said "Isolated records show that a physician here and there knew that a coronary thrombosis might cause a prolonged attack of angina even with recovery." It is known, however, that coronary occlusion must have been not uncommon in Germany over fifty years ago, otherwise Leyden⁴ would not have been able to recognize so many cases and write such an excellent description of its clinical features.

ETIOLOGY

In the vast majority of cases acute coronary occlusion develops at the site of an arteriosclerotic lesion. Its etiology is therefore intimately related with that of coronary arteriosclerosis and arteriosclerosis in general. As yet but little is known about the fundamental factors concerned in the production of arteriosclerosis and there would be little profit in attempting to review current hypotheses here. Nevertheless, various facts have been learned regarding certain characteristics and relationships of coronary arteriosclerosis and acute coronary occlusion that have some bearing on the etiology of these conditions.

It has been noted that there is little evidence to support the view that increase in the stresses and strains of life is a significant factor in the present incidence of coronary disease. On the other hand, this cannot be interpreted as meaning that physical or mental strains and overwork may not be important factors in the production of this disease and also of acute coronary occlusion. Age, sex and race are all known to have an important bearing. Coronary occlusion is relatively uncommon before the fifth decade. The greatest number of cases occurs in the sixth decade, although the actual percentage incidence may be higher in later decades. It is far more common in men than in women. The recent studies of Hedley⁵ and Johnston⁶ show that its frequency is much greater in the white than in the Negro race. Type of weather may be a factor in precipitating acute coronary occlusion, since the data collected by Wood and Hedley⁷ and Mullins⁸ appear to show that in Pennsylvania acute coronary occlusion is far more common in the winter months. Coronary arteriosclerosis is observed at necropsy in the majority of persons who had been either hypertensive or diabetic. The incidence of acute coronary occlusion is high for both of these diseases.

2 Hedley O F. A Critical Analysis of Heart Disease Mortality. J A M A 105 1405 (Nov 2) 1935.

There is considerable difference of opinion as to whether excessive use of tobacco favors the production of coronary occlusion. In this connection the observation of White⁹ that all his twenty-one patients who had coronary thrombosis before the age of 40 used considerable amounts of tobacco merits attention. There is no doubt whatever that ceasing the use of tobacco lessens the incidence of pain in certain patients with coronary disease, but in a large number no beneficial effect is observed.

The opinion is widespread that coronary disease selects as its special victims professional men and executives who are subject to heavy strain and responsibility. Analysis of the causes of death among American physicians in 1936 shows clearly the terrific effects of this disease and its complications in members of the medical profession.¹⁰ Similar careful analyses of other occupational groups for purposes of comparison are needed in the effort to obtain data bearing on certain possible etiologic factors concerning which there is no clearcut evidence at present. In addition, studies regarding the influence of heredity are needed.

The two other causes of coronary occlusion besides coronary arteriosclerosis and its sequelae which deserve mention are syphilitic disease of the coronary arteries and embolism. Coronary occlusion due to syphilis is not common unless aortic insufficiency is present.¹¹ Embolism is a comparatively rare cause of coronary obstruction. Saphir¹² reported three cases and was able to find only eleven other acceptable cases in the literature. Levy, Bruenn and Kurtz¹³ observed six cases in 2,877 necropsies.

PATHOGENESIS

The occurrence of myocardial infarction following coronary occlusion apparently depends on whether or not adequate collateral circulation is available for the area deprived of its customary blood supply. There have been considerable differences of opinion as to whether coronary arteries are end arteries or whether there is free anastomosis. Experimental work since the time of Cohnheim¹⁴ has indicated that collateral flow is extremely small and insufficient to support contraction in an area rendered ischemic by ligation of a main branch. It has been demonstrated by electrocardiography that myocardial injury currents develop within one or two minutes after even a small coronary vessel is obstructed,¹⁵ and recently Tennant and Wiggers¹⁶ showed that after coronary obstruction, contraction in the ischemic area stops within one minute. According to Wiggers,¹⁷ however, the experimental results do not preclude enlargement of minute potential communications or development of new ones when a main branch

is slowly occluded. Under such circumstances, altered pressure gradients distend "normally useless channels" and so furnish a supply of blood under pressure for newly growing vessels. Some such explanation must account for the frequent finding of coronary occlusion without myocardial infarction and particularly for such cases as the two reported by Leary and Wearn,¹⁸ in which complete occlusion of both coronary orifices had occurred without any signs of myocardial infarction.

Suggestions have been made that a new blood supply may be derived from thebesian vessels, from the vasa vasorum about the root of the aorta, from pericardial vessels or from reversal of flow in the venous system. However, it seems probable that the usual source of collateral circulation after myocardial infarction is the coronary circulation itself. That anastomoses are present has been shown by Gross and Kugel,¹⁹ even though all available evidence indicates that in normal hearts the collateral flow is extremely small. The assumption that collateral circulation develops only when it is required may explain the interesting observation by Beck and Tichy²⁰ that new blood vessels can be made to grow into the myocardium only when there is need for more circulation.

The experimental evidence suggests that the most dangerous type of clinical coronary occlusion should be sudden obstruction in an otherwise intact coronary circulation. Coronary embolism offers the chance of studying in the human being the effect of sudden obstruction in a previously healthy coronary system. Saphir¹² stated that sudden death is the striking feature of this condition. Of the fourteen patients he studied, twelve died suddenly. In striking contrast is the result of syphilitic occlusion of a coronary orifice, which is usually gradual in its development. Bruenn¹¹ stated that infarction is relatively rare in cases of syphilitic coronary occlusion. One may postulate, therefore, that among the important variables in human coronary occlusion, in addition to size and location of vessels obstructed, are the following factors:

1 The rapidity of development of occlusion. If occlusion occurs suddenly, more disastrous effects may be looked for than if it had occurred gradually, because of lack of time for the development of functionally useful collateral channels. However, in the majority of cases in which the clinical picture of acute coronary occlusion occurs, it seems probable that the final acute occlusive process (usually thrombosis) takes place in a vessel whose lumen has already been considerably reduced. The relative contribution of thrombosis to this process of occlusion may be the deciding factor in the severity of the attack.

2 The integrity of the circulation adjacent to the area supplied by the occluded vessel. Sprague and Organ²¹ stated that coronary thrombosis with closure limited to a single artery or branch of an artery is relatively rarely observed at necropsy. Saphir, Priest, Hamburger and Katz²² stated that in their cases whenever an infarct was found at least two branches were

involved. On the other hand, Moritz and Beck²³ found in their series of ninety-four cases that only the left coronary artery was occluded in 54 per cent, only the right in 13 per cent and both the left and the right in 33 per cent.

CLINICAL FEATURES

Smith, Rathe and Paul²⁴ have emphasized the intimate relationship between angina of effort, severe anginal pain (coronary occlusion) and paroxysmal dyspnea. They found that any one of these three conditions might be the first manifestation of coronary disease. Shortness of breath was the most common initial symptom and frequently persisted for months or years before other evidences of impaired cardiac function made their appearance. In approximately 50 per cent of the cases in which the initial manifestation was coronary occlusion, angina of effort later developed. The relation between coronary occlusion and paroxysmal dyspnea was found to be equally close.

There is a latent or symptomless period in coronary arteriosclerosis which may last a long time. During this period, physical examination may reveal nothing significant, although impairment of exercise tolerance may sometimes be discovered. Moreover, the electrocardiogram may or may not show significant changes. Many persons in this period are able to pass life insurance examinations without difficulty. The electrocardiogram may be abnormal, however, for years before clinical manifestations appear. Some patients complain of easy fatigability, gastro-intestinal disturbances and nervous irritability or insomnia long before the first definite evidence of cardiac disorder. The latter may take any of the following forms: (1) shortness of breath on effort, (2) angina pectoris, (3) acute coronary occlusion, either coming like a bolt from the blue or preceded by one or more so-called pilot attacks of anginal pain, less commonly (4) disturbances of cardiac mechanism such as auricular fibrillation or heart block and (5) paroxysmal dyspnea or trepopnea.²⁵

The various clinical phenomena of coronary disease may be conveniently classed in four categories: (1) abnormalities of cardiac mechanism, (2) angina pectoris, (3) acute coronary occlusion and (4) heart failure, including paroxysmal dyspnea. In any case these may be present singly or in various combinations. All may be present at the same time. Occlusion of coronary vessels and heart failure are the end results of progressive coronary disease. Acute coronary occlusion, however, with myocardial infarction should probably be looked on as an accident in the course of the disease. It is this condition, talked about so much by physicians and now feared by laymen, which makes the course of coronary disease so unpredictable.

SYMPTOMS

The outstanding symptom of onset is pain or severe distress. Most characteristic is the constricting or so-called viselike substernal pain. However, the distress may be described as a burning, boring, aching or choking sensation or a feeling as though something inside were being distended to the bursting point. Although these various types of distress are characteristically severe, sometimes they are mild. The various

locations of pain are well known, but left subscapular pain has not been sufficiently emphasized in the literature. Articles are to be found stressing the frequency of occurrence of coronary occlusion and myocardial infarction without pain.²⁶ The occurrence may depend to some extent at least on the rapidity of development of lesions. The tabulation of the anginal type of pain from histories, however, does not yield reliable data. If pain is mild or occurred some time in the past, patients frequently fail to volunteer a statement about it and, as a matter of fact, often seem to forget it. Furthermore, they will frequently deny having had pain, but on questioning will admit having suffered one of the other types of distress mentioned.

The anginal type of pain or distress probably occurs in nearly every case of acute myocardial infarction. Jervell²⁷ in his monograph stated that he found electrocardiographic evidence of acute myocardial infarction in but one patient who suffered no pain. I have seen only two or three patients with definite electrocardiographic evidence of recent infarction from whom a history of pain or other anginal type of distress could not be elicited.

On the other hand, the occurrence of prolonged and severe attacks of pain without subsequent clinical or electrocardiographic evidence of myocardial infarction is far from rare. In a number of cases reported of death following prolonged anginal attacks, necropsy failed to reveal evidence of important coronary disease or any other cause of death. Leary²⁸ has recently reported cases in which death was attributed to coronary spasm.

The characteristic signs often attributed to coronary occlusion—fall in blood pressure, narrowing of the pulse pressure, congestive failure (of which pulmonary congestion is the outstanding feature), fever, leukocytosis, friction rub, faint heart sounds, gallop rhythm, abnormalities of cardiac mechanism, increased sedimentation rate of red cells and electrocardiographic changes—are due to myocardial infarction rather than to coronary occlusion per se. The enfeeblement of cardiac action and the characteristic drop in blood pressure and narrowing of pulse pressure are probably due in part to the fact that, the infarcted area being no longer able to contract, the remainder of the heart muscle is unable to carry on efficiently. Tennant and Wiggers¹⁰ stated that the tendency to development of hypodynamic ventricular beats following coronary occlusion can be explained by loss of pressure due to systolic stretching of the areas in which contraction is enfeebled or absent. Thus, infarction not only lessens cardiac efficiency by putting out of commission part of the muscle but actually diminishes the efficiency of the surviving muscle through the dissipation of intraventricular pressure by the stretching of the injured area. This mechanism probably accounts in part also for the behavior of the blood pressure.

Fever, leukocytosis and increased sedimentation rate of erythrocytes are of no value in the differentiation of myocardial infarction from other lesions which may also produce these responses but may be of considerable help in the decision as to whether or not infarction has actually taken place after an attack of pain. Change in sedimentation rate is according to my experience the

most sensitive indicator of the three. The rate may become accelerated when fever is absent, the leukocyte count normal and the electrocardiographic appearance uncertain. Furthermore, it often remains abnormal for a considerable time after the electrocardiogram no longer shows evidences of acute injury or significant changes in successive serial tracings.

Friction sounds probably are not elicited in more than 25 per cent of cases. They are often evanescent, lasting only a few hours, occasionally they persist for a number of days. Since pericardial involvement may extend a considerable distance beyond the area of infarction, a friction sound need not necessarily originate directly over the myocardial lesion.

Tachycardia occurs in the majority of cases but is occasionally absent, particularly in cases of posterior infarction. Paroxysms of auricular fibrillation occur most frequently when the infarction is in the area of the anterior descending branch. Heart block tends to be associated with posterior infarction. Extrasystoles occur with infarction in any location.

ELECTROCARDIOGRAPHIC DIAGNOSIS

Prior to the addition of chest leads to electrocardiographic technic, it had been found that, while serial electrocardiograms often revealed the presence of acute myocardial injury, single tracings frequently failed to do so. In experimental coronary occlusion, significant changes often failed to make their appearance in the tracings although myocardial anoxemia was obvious. In an attempt to investigate this problem,²² it was found that in dogs injury currents could be recorded after obstruction of even a small coronary vessel, provided an electrode was placed on the area of its distribution. This indicated that the changes were present but that the limb leads did not always reflect them. It then occurred to experimenters to try chest leads. These had often been used in the past for other purposes, notably by Waller²⁹ and Lewis.³⁰ After Lewis's work it had been the practice for many years to use chest leads with one electrode over the auricular area whenever limb leads did not satisfactorily record auricular activity. When chest leads were applied to the study of acute coronary occlusion, first in experimental animals and then in patients, it was discovered that certain lesions which produced only equivocal changes or none at all in the limb leads showed spectacular injury currents in the chest leads.³¹ During the next few years much was learned as a result of the contributions of many investigators, notably F. N. Wilson, regarding the value and limitations of chest leads as a supplement to the conventional limb leads in the study of myocardial infarction, and various diagnostic patterns have been established.³²

Despite the advances in electrocardiography, this method should under no circumstances replace careful history taking and physical examination. An electrocardiogram is, however, such a valuable check on clinical examination in helping to establish or rule out the diagnosis that it should be used in every case in which coronary occlusion is suspected.

In certain recent studies of pathologic material, such as those of Sprague and Organ³³ and Saphir, Priest, Hamburger and Katz,³⁴ it would appear that electrocardiography had not made a good showing. Barnes³⁵ however stated that, when changes characteristic of acute myocardial infarction fail to develop, it will usually be found that tracings were not obtained in sufficient numbers or at the proper time in relation to acute occlusion, that multiple acute infarctions of the left ventricle were present, that bundle branch block obscured the changes, that pericarditis or pericardial effusion modified the electrocardiographic changes or that the tracing was made at about the time of death. The observations of Barnes were based on the use of limb leads alone. If chest leads are also used, one may modify the statements of Barnes in the following way. Serial tracings are not so often necessary, multiple acute infarctions³⁴ rarely obscure the diagnosis and the changes produced by pericarditis (more correctly speaking, by the myocarditis associated with pericarditis) can usually be differentiated from those produced by myocardial infarction.³⁵

During the past five years, since my co-workers and I have used chest leads as a supplement to limb leads, not a single patient of the thirty-two who have come to necropsy with an electrocardiographic diagnosis of acute myocardial infarction has failed to show such a lesion. Moreover, no patient studied post mortem thus far has shown acute infarction which electrocardiograms had failed to disclose. There has been one equivocal case—a case of dissecting aneurysm in which blood had infiltrated the right ventricle and caused acute destruction of muscle tissue. Nevertheless it is probable that certain small acute infarctions cannot be detected by electrocardiography, although none of these have been observed at our necropsies.

In the diagnosis of healed infarction, electrocardiography is not nearly so sensitive a method. The changes produced by infarction on the lateral or posterolateral wall of the left ventricle often disappear fairly rapidly so that they can no longer be recognized. The electrocardiographic pattern in the healed stage of posterior infarction is scarcely pathognomonic, although it may be regarded as reliable evidence of damage to this area of the heart. The pattern of the healed stage of anterior or apical infarction, however, tends to persist for a long time, at least in part, particularly in the chest leads, so that unmistakable evidence of the lesion may still be present many years after the attack.

DIFFERENTIAL DIAGNOSIS

Almost any condition capable of producing acute pain or distress in the same area as coronary occlusion may at one time or another present a problem in differential diagnosis. The list of conditions is greatly lengthened by the fact that the pain of coronary occlusion is often comparatively mild and the subsequent manifestations so slight as to escape attention. Thus, acute perforation of a gastric ulcer, gallbladder colic, acute pancreatitis, acute pericarditis or other acute mediastinal inflammatory condition, dissecting aneurysm of the aorta, pulmonary embolus, pleurisy or beginning pneumonia must be considered. Arthritis of the spine

or shoulder, spasm in the gastro-intestinal tract (esophagus, pylorus or colon), lesions of the diaphragm such as eventration, neuritis or functional neuroses may all lead to mistakes in diagnosis. Perhaps the most difficult of all is the differentiation between a prolonged attack of angina pectoris and acute coronary occlusion. There is an important border zone between these two conditions into which many cases fall. In some, serial electrocardiograms with chest leads and erythrocyte sedimentation tests show changes indicating that at least a slight myocardial lesion has occurred.

The electrocardiographic picture of acute coronary occlusion is simulated to some extent by a variety of conditions³⁶ which need not be mentioned here. However, most of the conditions which cause difficulty in the clinical differential diagnosis do not produce significant alterations in the electrocardiogram. Thus, combined clinical and electrocardiographic study with chest leads greatly simplifies the differential diagnosis.

SUBSEQUENT COURSE AND PROGNOSIS

Probably the great majority of early sudden deaths are due to ventricular fibrillation. Other causes of sudden death are embolism and ventricular rupture, although these conditions are less common causes and rarely occur until myocardial infarction is at least a few days old.

Among persons who escape sudden death in the early stage of acute coronary occlusion the commonest cause of death is myocardial insufficiency. The mechanism of heart failure, particularly in the first week, may consist of loss of ability to drive the blood forward through the systemic circulation. The patient may exhibit little or no dyspnea and no marked pulmonary edema, but the pulse literally fades out, in some cases the rate is rapid, but in others it is not increased. Possibly the loss of intraventricular pressure due to stretching of the infarcted area is partly responsible for this behavior.

Recurrent attacks of pain are common during the acute stage of myocardial infarction, and serial electrocardiograms may show that some of these attacks are accompanied by an extension of the area of infarction. Such recurrence may change what seemed to be a favorable course to an unfavorable one.

Hochrein and Schneyer³⁷ observed a mortality rate of 71 per cent in 226 cases, whereas Master, Jaffe and Dack³⁸ reported a mortality rate for the first attack of 8 per cent and a mortality rate for all attacks of 16.5 per cent. The figures of other observers range between these two extremes. It is generally agreed that the mortality rate is influenced by (1) age of the patient (the rate being lower for relatively young people than for the older age groups), (2) number of attacks (mortality is much less for the first than for subsequent attacks), (3) severity of clinical manifestations (higher mortality for severely ill patients) and (4) electrocardiographic appearances (according to Conner and Holt³⁹ the patients who show minimal electrocardiographic abnormalities have a more favorable outlook than those with marked electrocardiographic changes). According to our experience, patients with evidences of

posterior infarction have a better prognosis than those with anterior infarction.⁴⁰ Hospital statistics may fail to present the complete picture of the disease because (1) some patients die before they can be moved to a hospital, (2) others are too sick to be moved and (3) still others do not regard themselves as sick enough to go. Furthermore, clinical sensitization to the diagnosis, combined with careful electrocardiographic study, will uncover many mild cases in office practice that would otherwise be overlooked.

The course of the patients who survive an acute attack of coronary occlusion is on the whole unfavorable, although every one of experience has a few patients who have done remarkably well. One of the great hazards is the danger of subsequent attacks. Conner and Holt's figures,³⁹ which indicate that at least 40 per cent of the persons who survived their first attack suffered subsequent attacks, are admittedly inadequate because some patients had died prior to the follow-up study and others could not be traced.

The inevitable result of coronary occlusion is permanent impairment of cardiac function. Many patients never recover sufficiently to return to work after the first attack. Each subsequent attack survived causes further crippling. Conner and Holt found that at the end of five years only 15 per cent of their patients could be regarded as well and at the end of ten years only 3.4 per cent. The results reported by Willius⁴¹ seem a little better, but he was dealing with a selected group.

TREATMENT

In the early stages of the attack the two conditions that may urgently require treatment are intolerable pain and circulatory collapse. For the pain, nitrites are usually useless and may be dangerous. Hypodermic injections of morphine or other opiates are required. Although morphine is not to be spared so long as pain is severe, overdosing may increase the hazard by depressing respiration. The relief of flatulence, the application of heat or counterirritation to the chest and the administration of oxygen are measures sometimes helpful in relieving pain.

In the treatment of circulatory collapse many physicians inject such drugs as caffeine, atropine, digitalis or one of the various proprietary preparations highly recommended by their manufacturers. None of these drugs have more than dubious value, most are useless. Epinephrine may be dangerous. The patient should be kept warm by such measures as the use of hot water bags and blankets. If alarming failure of the circulation occurs, an intravenous injection of from 20 to 40 cc of 50 per cent dextrose may be given slowly from time to time. Fluid and sweetened drinks given freely by mouth at this stage may start vomiting. It is best to give them in small and limited amounts. An oxygen tent may be helpful. Venesection seems to be a two edged sword, and the indications for its use are not yet clear.

Smith, Rathe and Paul⁴² advised that the administration of theophylline be instituted promptly after coronary occlusion and continued for a long time. Although there is a good theoretical indication for its use, there is considerable doubt as to how much it

helps. Given intravenously, it is said to stop acute pain in some patients. The recent studies by Starr, Gamble, Margolies, Donal and Joseph⁴³ suggest that it is one of the most powerful of heart stimulants. Stimulation may be desirable in certain cases and not in others. Quinidine sulfate has been advised in the early stages in doses of 0.1 Gm. twice a day⁴⁴ up to 0.2 Gm. three times a day⁴⁵ in the hope of preventing paroxysmal ventricular tachycardia or ventricular fibrillation.

Digitalis may properly be used in the treatment of paroxysmal auricular fibrillation if it persists for many hours or appears to be adding to serious heart failure. Mild grades of congestive failure do not require digitalis. When given it should be administered much more cautiously than in the treatment of other types of congestive failure. Bellet, Johnston and Schechter⁴⁶ showed that, in dogs after the production of infarction, digitalis was less well tolerated than in normal controls. McMillan and Bellet⁴⁷ have shown that in patients with severe coronary disease, digitalis in full doses may be dangerous.

Most writers emphasize the importance of a diet small in bulk and consisting of easily digestible foods during the acute stage. As a matter of fact, many patients desire little or no food at all during this stage. Master, Jaffe and Dack⁴⁸ recommended a prolonged regimen of a low caloric diet and undernutrition, believing that it lessens the work of the heart without decreasing its efficiency and that mortality is thereby lowered.

All observers appear to agree on a minimum of from four to six weeks in bed for patients who do well and a much longer period for those who do not convalesce smoothly. The principle of rest should be continued after the patient leaves his bed. I attempt to keep even those who do best away from work for at least three months and have them begin on a part time basis with as many holidays as possible. Others should be restricted for even longer periods. There is good reason to believe that a long period of rest permits the heart to recover reserve strength much better than a short rest period and thus postpones or averts the occurrence of subsequent failure.

Little is known as to how to prevent recurrent attacks. My impression is that the patients who are willing to lead their lives on a restricted plane, avoiding severe physical and mental strains, being careful in their habits of eating, drinking and relaxation and obtaining abundant rest, do better than patients who are unwilling to submit to restraint. It has also seemed to me that those who stop entirely the use of tobacco get along better. However, whether this is due to the fact that tobacco is harmful to patients with coronary disease or to the fact that those who stop the use of tobacco are more careful in other respects would be difficult to decide.

Interesting new developments are the application of surgical procedures to the treatment of coronary disease. Total thyroidectomy has been recommended for

certain types of angina pectoris and heart failure⁴⁹. More recently, attempts have been made to improve collateral coronary circulation by surgical procedures⁴⁹. Whether either of these developments wins for itself a definite place in the treatment of coronary disease remains to be decided in the future.

SUMMARY

The concepts of acute coronary occlusion chiefly emphasized in this discussion are the following:

1 The disease is one of the major causes of death after the fourth decade. There is no evidence on which to decide whether its frequency is increasing.

2 Little is known regarding its fundamental etiologic factors. Certain definite relationships to age, sex, race, diabetes mellitus and hypertension have been discovered. The influence of heredity, habits of life, occupation, physical and mental strain, or overwork, have been much discussed but have not been clearly demonstrated.

3 The evidence at hand suggests that collateral coronary circulation is not active in normal hearts and apparently develops only when there is need for it. The course of events after coronary occlusion, particularly the occurrence of myocardial infarction, depends on such factors as the size and position of the vessel obstructed, the rapidity of development of occlusion and the integrity of the adjacent circulation.

4 Acute coronary occlusion is usually an accident in the course of coronary arteriosclerosis.

5 Progress in the technic of electrocardiography has recently been made and the diagnostic value of this procedure enhanced.

6 Combined clinical and electrocardiographic study is valuable.

7 There is a wide range in the figures obtained by various workers for mortality during attacks. Statistics show that, among patients who survive attacks, excellent recovery is the exception rather than the rule. The hazard of cardiac deterioration, subsequent attacks or both is great.

Invention, Communication and Social Habituation—Before naming or discussing these three basic processes which characterize man, let us point out that these depend in turn upon three structural evolutionary changes which occurred either simultaneously or in very close succession, namely, the assuming of the upright position when man became a ground, rather than an arboreal, animal, the development of language vocal organ apparatus and the spurt in the growth of the great forebrain. The upright position freed the forelimbs, making possible the growth and development of manual activity; the utilization of primitive tools, in fact the sum total of all that we call *invention*; and *invention* is the first great noninherited basic process that has made civilization and culture possible. The growth of language from its primitive symbolism to its present complexity made possible *communication*, the second major basic process; and the development of these two in association and integration along with the new brain growth and intelligence brought about *social habituation* (Warden), the greatest of all biological and cultural characteristics, possessed by no lower animal except in its most rudimentary form. All that we gain by *invention* can be passed on by *communication* to be utilized by others in successive generations for social adaptation.—Lewis, Nolan D. CORONARY DISEASE IN YOUTH

COMPARISON OF 100 PATIENTS UNDER 40
WITH 300 PERSONS PAST 80

R EARLE GLENDY, MD

SAMUEL A LEVINE, MD

AND

PAUL D WHITE, MD

BOSTON

It has become apparent in recent years that atherosclerosis, particularly of the coronary arteries, can no longer be regarded as the natural result of old age or as a medical curiosity when it occurs in the early decades of life. It is no longer rare in practice to encounter men under 40 who have fallen victim to disease of the coronary arteries, as manifested by coronary thrombosis or uncomplicated angina pectoris or both, long before they have reached the peak of their usefulness.

It seems important, therefore, to determine how frequently serious coronary disease attacks persons in youth and early middle age and what its clinical characteristics in such persons may be. Furthermore, if clues are to be discovered that may aid in its prevention or disclose any underlying causative factors, exclusive of the aging process, the younger patients must be studied carefully.

It was with these thoughts in mind that we began our investigations nearly three years ago. During the intervening time we have been able to collect from various sources¹ material on 100 patients under 40 with coronary disease, and from a considerable number of these patients, by means of a questionnaire, we have obtained certain data regarding their manner of living. In addition we have assembled data on the mode of life of 300 persons living at ages past 80, the assumption being that persons who have attained such advanced ages constitute a highly selected group whose vital organs and functions have been much better than those of the average man. On the other hand, the younger group are marked because of the premature occurrence of serious heart disease which has until recently been regarded as the result of old age. The clinical analysis of the young group and the comparison in the manner of living of the two groups form the basis of this paper. A preliminary report was published in 1935.² So far as we have discovered, no one has as yet reported a comparison of these two groups.

LITERATURE

Among reports of cases of coronary disease published in the literature we found a considerable number on patients under 40, usually incorporated in studies covering all age groups. It has been difficult to determine from these reports just what the actual incidence of coronary diseases is in the third and fourth decades

From the Cardiac Clinic and Laboratory of the Massachusetts General Hospital.

Because of lack of space this article is abbreviated in *THE JOURNAL*. The complete article appears in the authors' reprints.

A large part of the material for this paper was assembled while Dr. Glendy was Dalton Scholar at the Massachusetts General Hospital 1934-1935.

Read before the Section on Practice of Medicine at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1937.

1 The following hospitals and individual physicians in Boston cooperated, making possible the collection of data on such a large series of young patients with coronary disease: the Peter Bent Brigham Hospital, the Boston City Hospital, the Beth Israel Hospital, and Drs. H. B. Sprague, Louis Wolff, H. B. Levine, Sylvester McGinn, R. B. King, A. G. Brailey, R. S. Palmer, Jacob Lerman, and Alfred Kraines.

of life. Lack of space will not permit the lengthy review of the literature, which will appear in the reprints of this paper.

For centuries the subject of longevity has engaged the interest of medical and nonmedical observers the world over. Most of the earlier works on longevity are concerned chiefly with the tabulation of lists of aged folk, observations on their remarkable abilities, and philosophical writings. Recorded among these are such startling instances of longevity as that of Henry Jenkins, a Yorkshureman, who is said to have died in 1670 at the age of 169, having assisted, when a boy, in conveying arrows to Flodden Field at the battle which was fought 158 years previously.²⁷

More systematic and scientific observations on longevity began to appear in the latter part of the nineteenth century, of which Humphrey's²⁸ monograph on "Old Age" is a good example.

In recent years Pearl and Dublin and their associates²⁹ have made many valuable observations on the biology and diseases of senescence and the factors influencing longevity in this country.

DEFINITION OF CORONARY DISEASE

Atherosclerosis with a variable amount of fibrosis is the main problem in coronary disease in youth and middle age.²⁹ Evident infectious lesions of importance are rare and embolism is still rarer.

Disease of the coronary arteries was recognized in this study by the occurrence of coronary thrombosis, the diagnosis of which is usually easy, angina pectoris without any evidence of syphilis, valvular disease, thyrotoxicosis, severe anemia or congenital defects, and by the finding of characteristic electrocardiographic changes, which demand careful analysis, particularly in young persons. Furthermore, when the diagnosis of angina pectoris was made it was inferred that significant atheromatous changes were present in the coronary arteries and that the patient was subject to sudden death or to attacks of coronary thrombosis. A careful attempt was made to select only cases of uncomplicated coronary disease.

MATERIAL

It became evident soon after this study began that coronary disease under the age of 40 occurs so infrequently in the experience of any one clinic or individual as to make the compilation of data from such sources of limited value. Therefore, after exhausting the possibilities of our own private practice we turned to the various large hospitals in Boston and appealed to individual physicians for suitable cases. In this way 100 cases of undoubted coronary disease occurring under the age of 40 were assembled according to the diagnostic criteria listed. Cases were at once excluded when there was the slightest question as to the diagnosis or when the possibility of a complicating factor seemed to enter into the picture. Table 1 shows the ages and sex distribution in these cases.

For comparison with the young group with coronary disease, data were assembled on 300 persons living past the age of 80. These people were chosen primarily for their longevity, and such factors as race (except that they are all white), geographic or residential location and other factors which may or may not influence long life were not taken into consideration. Their names were obtained from newspaper clippings, various directories, lay and professional associates and the old folks themselves, who were glad to give us in turn the names of aged friends or relatives.

TABLE 1—Ages and Sex Distribution of 100 Patients Under 40 with Coronary Disease*

Age at Onset	Men	Women	Total

30-34	17	0	17
20-29	7	1	8
	96	4	100

* Average age men 35.7 women 33.2 entire series 35.6

Information was obtained from all the older group and from the majority of the survivors in the young group by means of an extensive questionnaire, too lengthy for publication here. It is fashioned for the most part after the questionnaire used by Pearl^{28†} in his studies of longevity but is more detailed, particularly regarding diet and personal habits and hygiene. Answers to the various questions yielded information from both groups about their birthplace, racial stock, place of residence, occupations, ancestral, family and marital history, use of tobacco and alcohol, exercise, nervous sensitivity and strain, dietary habits, hygiene, body build and past history of infections and operations. The results of this study are given in an analysis to follow later.

ANALYSIS OF 100 CASES OF CORONARY DISEASE OCCURRING UNDER THE AGE OF 40

The diagnosis of coronary thrombosis was established clinically in seventy-eight cases of the present series, with postmortem confirmation in ten, seventy patients had angina pectoris, forty-nine had both conditions. Twenty-nine had coronary thrombosis without angina pectoris and twenty-one angina pectoris without coronary thrombosis. One patient had neither angina pectoris nor clinically evident coronary thrombosis but showed electrocardiographic evidence of serious coronary disease.

Incidence—Fifty-two of the total of 100 patients were from our own private practice. They were observed among a total of 3,376 patients with disease of the coronary arteries. This makes an incidence of 1.54 per cent.

It must be kept in mind that this figure represents only a selected group of persons who sought medical advice because of symptoms or signs relating to the heart. The true incidence of coronary disease in the young and the old in the community can be determined only by careful examination, including electrocardiography, of thousands of persons unselected except that they include farmers, laborers, business and professional men and housewives. Such a survey should be done in various parts of the world.

Clinical Features—The clinical characteristics of coronary disease under the age of 40 differ very little from the disease as it is generally encountered. There are, however, certain striking exceptions.

Sex Incidence The most outstanding exception is the overwhelming preponderance of men over women. Ordinarily in patients with coronary disease three or four men are seen to one woman, but the preponderance of men over women in the young group is twenty-four to one. This contrast makes one think that whatever the factors are underlying the development of coronary disease they must be working with unusual force in these young men, whether they are hereditary influences, the effect of urban life, the use of tobacco or other conditions.

Hypertension The incidence of hypertension was relatively much lower in the young group than in persons of all ages with coronary disease. Hypertension was considered to be present if the systolic blood pressure measured 160 mm of mercury or more or the diastolic pressure 110 mm or more. The incidence of hypertension in our series was 16.6 per cent for ninety-six patients whose blood pressure was known, whereas in a group of all ages reported by White and Bland³⁰ the incidence was 36.4 per cent in 500 patients with angina pectoris and 25 per cent in 200 patients with coronary thrombosis. Of additional interest is the fact that three of the four women with coronary disease under the age of 40 had hypertension. Only thirteen of ninety-two men (12.5 per cent) had hypertension. This is in agreement with our own observations and those of others³¹ that coronary disease in women under the age of 50 in the absence of hypertension is uncommon. Forty-four per cent of the young group with hypertension are dead. This figure is only slightly higher than the percentage mortality for the entire group (36 per cent) at the present time but indicates that the presence of hypertension may have a slightly unfavorable influence on the duration of life.

Diabetes and Buerger's Disease Diabetes was present in only two cases of the present series and Buerger's disease in an equal number.

Size of the Heart Cardiac enlargement was present in 37 per cent of our young group. The size of the heart was questionable in 9 per cent and normal in

TABLE 2—Ages and Sex Distribution of 300 Persons Over 80*

† The manner of selection no doubt accounts for the preponderance of men.

54 per cent. In the series of 500 patients with angina pectoris and 200 patients with coronary thrombosis reported by White and Bland, 63 per cent of the former and 74 per cent of the latter had cardiac enlargement. It is apparent from these figures that considerably more of the young group have hearts that are normal in size.

Electrocardiographic Observations In general the electrocardiographic appearances were much the same as for older patients with coronary disease.

Cardiac Neurosis Cardiac neurosis is frequently encountered in patients with coronary disease, par-

ticularly those who fall victim to the disease in early life. We have called attention to this subject in two recent communications.³²

Prognosis—When we come to consider the prognosis of coronary disease in early life we find it just as difficult and as uncertain as every student of coronary disease has found it in the past. Naturally one would expect a youthful person, other things being equal, to withstand any disease process with fewer complications and for a longer time than one of advanced years. To a certain extent this is true of young persons with coronary disease.

Of the 100 patients in our series thirty-six have died and sixty-four are alive. Recent reports were obtained regarding all the patients. Of the thirty-six who died, thirty-three died of cardiac disease, eighteen very suddenly, presumably of coronary thrombosis, and two of congestive failure. Of the remaining three, two died after operations and one of pneumonia. There were only two immediate fatalities, one of the patients lived for seven hours and the other for three days. Both these deaths were due to coronary thrombosis.

additional proof were needed to validate the accuracy of the clinical diagnoses, it is furnished by the finding of gross changes in the coronary arteries of each of our ten patients examined post mortem.

Of the sixty-four patients still living, forty-two are working full time at their usual occupations. One half of this number are free from symptoms, the other half continue to have mild anginal distress. Nine patients are able to work only part time on account of angina pectoris, seven are totally incapacitated for work because of severe angina pectoris, one is unable to work because of congestive failure and five have not yet attempted normal activity since recent attacks of coronary thrombosis.

When we consider coronary disease under the age of 40 regardless of the nature of onset or clinical course (table 3), the prognosis is better by two and one-half years than in the average case of coronary thrombosis and nearly the same as in the average case of angina pectoris. For coronary disease under the age of 30 the average duration of life of those who have died and of the survivors (seven and four-tenths

§ 82 per cent of the deaths were sudden.

without antecedent symptoms of coronary disease. The remaining patients, both living and dead, survived for periods varying from a few months to twenty years. In contrast to the immediate mortality for coronary thrombosis of 26 per cent for our series, Conner and Holt⁴ found the immediate mortality for the first attack to be 16.2 per cent for 287 patients of all ages with coronary thrombosis. Although immediate fatality without antecedent evidence of coronary disease was rare in our young group, 50 per cent of the thirty-six deaths which occurred were sudden deaths. The same incidence of sudden death was found by Eppinger and Levine³³ for 141 patients of all ages with angina pectoris. It would appear, therefore, that young patients with coronary disease are just as susceptible to sudden death as any person with coronary disease, although they may live a little longer, as will be shown later. It is also evident from these observations that such patients almost invariably die of heart disease, either angina pectoris (sudden death), subsequent coronary occlusion or congestive heart failure. This fact alone should serve to dispel the skepticism with which the diagnosis of coronary disease in early life has been regarded by some authorities in the past. If

years) far exceeds the average period of survival in any age group regardless of the clinical manifestations.

It is also seen from table 3 that, in general, the average duration of life from onset to death and the elapsed time from the onset of symptoms in the survivors is greater for our young group with coronary thrombosis and angina pectoris than for similar groups of all ages reported by White and Bland. The accumulation of material for our young series has taken place over a longer period, and much of it has come under observation since the publication of White and Bland's figures. The two series are therefore not strictly comparable as to time relationships. Nevertheless, we find the comparisons of percentage mortality and duration of survival for the living and the dead in the two series useful and of interest.

For the young group with coronary thrombosis who have died the period of survival from onset to death (3.6 years) is nearly two and one-half times as great as for the group of all ages (1.5 years), a better figure, to be sure, but still not very encouraging. The average duration from the onset of symptoms for the survivors (4.5 years) is also greater for the young group by more than a year than for the group of all ages (3.2 years). This gives an average duration of life of 4.3 years for the entire but uncompleted series of 100 young people with coronary disease as contrasted with an average of 2.4 years for 195 patients

³² Glendy, R. E. and White, P. D. The Recognition and Treatment of Cardiac Neurosis. *M. Clin. North America* 21: 449 (March) 1937. The Growing Importance of Cardiac Neurosis. *Ann. Int. Med.* 10: 1624 (May) 1937.

³³ Eppinger, E. C. and Levine, S. A. Angina Pectoris. Some Clinical Considerations with Special Reference to Prognosis. *Arch. Int. Med.* 53: 120 (Jan.) 1934.

of all ages. This does not mean, however, that it is any advantage to have coronary disease in youth.

In comparing angina pectoris in early life with the condition at all ages, one finds that the prognosis as expressed in years is only slightly better for the younger patients. For those who have died the average duration of life from onset to death was 52 years, as compared with 44 years for persons of all ages. The average duration from the onset of symptoms for the survivors was 52 years for the younger group and 51 years for the group of all ages. The averages for both series were 52 years and 49 years, respectively. The reason that the younger patients with angina did not live any longer than the average for the group of all ages is that so many of the former (70 per cent) had attacks of coronary thrombosis whereas only 25 per cent of the latter suffered from this complication.

In subdividing the patients with coronary disease under the age of 40 for further analysis, one sees, from table 3, that twenty-one had angina pectoris without evident coronary thrombosis during the period of clinical observation. Although the percentage mortality to date for this group has been high (53 per cent) and the deaths frequently sudden, the patients have lived longer (average, 64 years for the entire series) than any other group except the eight under 30, who have lived an average of 74 years.

Coronary thrombosis uncomplicated by angina pectoris occurred in twenty-nine cases (37 per cent of seventy-eight cases of coronary thrombosis). This figure seems unusually high and, if borne out by subsequent observations, would appear to afford one of the exceptions in the manifestations of coronary disease as we usually see it. According to our experience it is comparatively uncommon in the general run of cases to find absence of anginal distress after coronary thrombosis. In reviewing the clinical history of the young patients, however, one finds that quite a number, particularly among those who had coronary thrombosis in the twenties, are normally active without symptoms and that a few even engage strenuously in such sports as tennis, squash and swimming with no harmful effects. This may be explained in part by the ability of the coronary circulation in early life to regain an adequate function after an insult such as coronary thrombosis, but this observation is offset somewhat by the fact that the average duration of life from onset to death, for ten patients in this group who have died, is only slightly longer (18 years) than for patients of all ages with coronary thrombosis (15 years). The duration from the onset of symptoms for the survivors is 45 years, and the average for the entire twenty-nine patients is 36 years.

Coronary thrombosis and angina pectoris combined were present in forty-nine of our series of 100 cases. From our figures it appears that the combination of the two affords a better prognosis than coronary thrombosis without angina pectoris and that patients who have angina pectoris before coronary thrombosis live slightly longer than those of whom the reverse is true. To be sure we are dealing with a relatively small number of cases, which may account in part for this unexpected finding, but it is possible that the presence of angina pectoris as a constant warning signal may act to make the patient lead a more exemplary life and therefore improve his prognosis.

Postmortem Examination—The ten patients who were examined post mortem all showed more or less atheromatous degeneration, with a variable amount of

fibrosis, and partial or total occlusion of the left coronary artery or one of its main branches. The right coronary artery showed only slight atheromatous changes with two exceptions, and in both these cases advanced changes were present with thrombosis and myocardial infarction.

It is apparent from the foregoing observations that degenerative changes of a remarkable degree do exist in the coronary arteries at relatively early ages. A detailed account of the changes characteristic of coronary disease in early life is found in the work of Leary.²⁹

COMPARISON OF 300 PERSONS LIVING AT AGES PAST 80 WITH 100 PERSONS UNDER 40 WITH CORONARY DISEASE

When we turn to our series of 300 healthy old men and women and compare them in race, ancestral longevity, residence, occupation, exercise, diet, use of tobacco and alcohol and past history of infections with the group of 100 patients with coronary disease under the age of 40 we find only a few prominent differences, and these we must not unduly emphasize until information from many more cases is available.

There is neither time nor space here for the many tables used in the compilation of our data. They have therefore been omitted. To persons who want more detailed information we shall be glad to furnish it by personal communication. When percentages are given, unless otherwise stated, they apply to the entire series of 300 old folks or 100 young patients with coronary disease, as the case may be.

Race Stock—Relatively far more (90 per cent) of the old group, 80, 90 and 100 years old, than of the young group with coronary disease are of British stock. This is probably the result of our method of selection and of other factors, such as time of immigration. Only 44 per cent of the young group are of British stock, 39 per cent are Jewish (mostly Russian born) and the remaining few are largely of Italian, Syrian or Greek stock. The incidence of coronary disease in young Jewish people as shown here demonstrates once more the high degree of vascular vulnerability in this race. However, the method of selection of the young group may have resulted in a somewhat higher incidence of Jewish people. Among those scattered cases occurring at various hospitals and under the care of individual physicians it has been impossible to make an accurate determination of the racial incidence of coronary disease. However, in the private practice of two of us the incidence of Jewish persons is 17.5 per cent and 62 per cent respectively, Jewish patients of all ages comprise 19 per cent and 37 per cent respectively, and those under 40 number 31 per cent and 59 per cent respectively of all cases of coronary disease. Therefore, in confirmation of our figure of 39 per cent Jewish patients among the young coronary cases, it is significant that in early life the percentage of Jewish patients with coronary disease exceeds by far the number encountered in the later decades of life.

Ancestral Longevity—It has been known for a long time that heredity, among other things, has an important rôle in bringing about long life and that to have long-lived ancestors is desirable. Our series of old folks bear this out once more.

Our data regarding the longevity of fathers and mothers of members of both groups is striking. The average at death of the fathers of the old folks (70.8 years) was higher by nine years than the figure for the young group (61.8 years), and for the mothers of

the old folks the average age at death (71.4 years) was greater by fourteen years than the figure for the young group (57.2 years). The mothers of the old people outlived the fathers on an average of less than a year, whereas for the young group the reverse is true but the difference in average ages is more striking, the fathers living nearly five years longer. This agrees with the previous observations of Eppinger and Levine³³ on persons with angina pectoris. They suggested that the defect of vascular vulnerability is transmitted more prominently by the female than by the male parent.

Place of Residence—The majority of the old group (70 per cent) have resided in small towns, villages or the country, in contrast to the young group, whose residence has been almost wholly (82 per cent of ninety-two persons) in large cities.

Life tables for 1930 compiled by the Metropolitan Life Insurance Company³⁴ regarding the expectation of life at specified ages show that the life of the rural dweller in the United States is, on the average, four or five years longer than that of the urban resident. In 1901 the average was approximately nine years longer for the rural resident. Industrialization, with a shift in population, has no doubt been responsible for this changing mortality. It is apparent therefore that the majority of our young patients with coronary disease are handicapped to the extent of four or five years from the very outset.

Occupation—Slightly more than half of the old men were professional (30 per cent) or business (23 per cent) men, and the remainder (47 per cent) were of the so-called working class (e.g., farmers, carpenters and mechanics). About three fourths of the young men were professional (19 per cent) or business (50 per cent) men or otherwise engaged in some sedentary work (8 per cent). The remaining fourth were artisans. None were farmers. The number who designated themselves as day laborers was quite small in both series.

The women in both groups were predominantly houseworkers, with the exception of a few unmarried ones who in their earlier years worked as teachers or seamstresses and later as housekeepers. The four women in the young group were all housewives.

Exercise—As for exercise, there is a wide difference in the two groups. Ninety-one per cent of the old group had exercised considerably to well beyond middle life and many of them, particularly those who had worked hard outdoors, were still moderately active. One man of 86 reported skating several miles daily during the winter when the river was frozen over. Fifty-two per cent of sixty-seven of the young group were sedentary in habit and exercised very little, 31 per cent exercised moderately and 16 per cent much. A considerable number of the young group had been strenuously active in athletics in their younger days, but only a few continued to exercise regularly. The types of occupations in which these young persons are engaged perhaps account in part for their habits of exercise. Long hours and confining work leave them little free time for adequate exercise, so important in maintaining a good state of health.

Diet—The older group claims to have eaten more moderately than the younger group, but here a difficulty arises in that a man past 80 whose diet is almost always frugal may have forgotten an enormous appetite present in youth. However, when we take into consideration

the higher proportion of heavy-set or fat persons in the young group as compared with the old group in early life, the chances are that the young group have in fact eaten more heartily.

Of late it has been suggested that certain foods rich in cholesterol, chiefly eggs, milk and butter, eaten in adult life in excess may be a factor in the production of atherosclerosis.³⁵ It is true of our two series that eggs and milk were consumed in somewhat greater quantity and with greater regularity by the young patients with coronary disease than by the old folks, but many of the aged who are still well and active stated that they had consumed eggs and milk regularly every day for most of their lives.

Our data, therefore, do not permit us to draw any definite conclusions regarding diet in the production of coronary disease, although further study may show that, as with diabetes, it is the combination of faulty metabolism plus faulty diet that is important.

Use of Tobacco—Owing to the almost total abstinence from tobacco and alcohol by the women, only men are considered in this comparison and the one to follow.

Although a fair number of the old folks (43 per cent) used tobacco moderately, there were far more total abstainers (44.2 per cent) than in the young group (6.7 per cent of eighty-eight persons) and far fewer heavy users of tobacco in the old group (4.2 per cent) than in the young group (5.8 per cent of eighty-eight persons). Including the occasional users of tobacco, 55.8 per cent of the old group were smokers and 44.2 per cent nonsmokers, but in the young group 93.3 per cent were smokers and 6.7 per cent nonsmokers.

This striking difference between the two groups in the use of tobacco is of interest, and the young group affords an exception to the observations reported in 1934 by White and Sharber³⁵ on a series of 750 patients of all ages with angina pectoris compared with a series of 750 persons without angina pectoris of the same ages, proportion of sexes and walks of life, which showed relatively little difference in their past use of tobacco, with few exceptions. It would appear now that the younger patients with coronary disease (angina pectoris) may fall among the exceptions.

Alcohol—In the use of alcohol the differences between the old folks and the young group are far less striking than in the use of tobacco. Nearly 50 per cent of the old group were total abstainers from alcohol, in contrast to 30 per cent in the young group. The occasional, moderate and heavy users of alcohol were slightly greater in number in the young group. Among the old men 83.7 per cent were total abstainers or occasional users of alcohol, in contrast to 74.8 per cent in the young group. The opinion, held by many, that alcohol may act as a prophylactic in the prevention of arteriosclerosis is neither disputed nor confirmed by these figures.

History of Infections—When we come to the history of infections it is surprising to discover that with the exception of diphtheria and pneumonia the older group suffered considerably more from severe infections than did the younger.

It would appear therefore that infections do not have an important role in the early production of coronary disease.

Body Build, Nervous Sensitiveness and Stature—The characteristic habitus of 83 per cent of the old group in early life was average or thin and lean, 15 per

³⁴ Rural versus Urban Longevity. Metropolitan Life Insurance Company Statistical Bull. 16:1 (July) 1935.

³⁵ White P. D. and Sharber Trimble. Tobacco, Alcohol and Angina Pectoris. J. A. M. A. 102:655 (March 3) 1934.

cent were heavy set and only 2 per cent distinctly fat. In contrast nearly 70 per cent of seventy-eight patients in the young group were robust in stature and more than one third of these were distinctly fat. Approximately 25 per cent of seventy-eight patients in the young group were of average build, and a few were thin and lean.

Nervous sensitiveness and nerve strain were considerably greater in the younger group and practically negligible in the older group. No doubt this is due to the fact that the young people were almost wholly urban dwellers and subject to the strenuous competition and other stresses of modern life in a large city. Racial factors may also enter here.

SUMMARY AND CONCLUSIONS

Approximately 17 per cent of all coronary disease occurs in persons under 40. The ratio of men to women is 24:1, which is about six times greater than is generally encountered. Hypertension is less common than in persons of all ages with coronary disease, but was present in a high proportion of the women (three out of four) in the young group. Its influence on the prognosis is slightly unfavorable. Considerably more of the young people (54 per cent) than of the patients of all ages with coronary disease have hearts that are normal in size. In general the electrocardiographic observations were much the same for the young as for older patients, with perhaps fewer permanent or serious conduction defects. Such conditions as diabetes and thrombo-angitis obliterans were relatively uncommon. Cardiac neurosis was fairly common as a complication.

The prognosis of coronary disease in early life is just as difficult and as uncertain as every student of coronary disease has found it at any age. Of the 100 patients in our series thirty-six have died and sixty-four are alive. There were only two immediate fatalities, both from coronary thrombosis. Of the thirty-six who died, thirty-three died of cardiac disease, eighteen died very suddenly, thirteen of evident coronary thrombosis and two of congestive heart failure. Of the sixty-four patients still living, forty-two are working full time. The remainder are partially or totally disabled because of cardiac symptoms (chiefly angina pectoris). The prognosis of coronary disease under the age of 40, regardless of the nature of onset or the clinical course, is better by two and one-half years than in the average case of coronary thrombosis and nearly the same as in the average case of angina pectoris. For coronary disease under the age of 30, the average duration of life of those who have died and of the survivors (74 years) far exceeds the average period of survival for any other group regardless of the clinical manifestations.

In comparing coronary thrombosis in youth and at all ages one finds that the average period of survival is 43 years for the former and 24 years for the latter, both living and dead. The same comparison of angina pectoris in youth and at all ages shows the difference to be very slight, the period being 52 years for the former and 49 years for the latter. This is accounted for by the much greater incidence of coronary thrombosis in the young group with angina pectoris. The average period of survival for persons with angina pectoris alone in early life (64 years) is better than for persons with coronary thrombosis alone (36 years), but it would appear from our figures that the combination of the two diseases affords a better prognosis (47 years) than coronary thrombosis alone and that persons who have angina pectoris before

coronary thrombosis live slightly longer (53 years) than those of whom the reverse is true (41 years).

A comparison of the mode of life of our 100 patients with coronary disease with that of 300 persons living at ages past 80 revealed a few prominent differences, but these must not be emphasized until information from many more cases is available. Relatively far more (90 per cent) of the old folks than of the young group with coronary disease were of British stock, but here selection and other factors, such as time of immigration, may well enter. There were no persons of Jewish extraction in the older group, whereas 39 per cent of the young group were Jewish. Long-lived ancestors were more common to the aged group. However, it is of interest that the fathers of the younger group who died outlived the mothers by an average of five years. This relationship is usually reversed by several years. The majority of the old group have resided in small towns, villages or the country, in contrast to the young group, whose residence has been almost wholly urban. The younger group consisted largely of business or professional men. Among the old folks the occupations requiring physical activity were more common. A large number of the old group had exercised considerably to well beyond middle life. The young group were for the most part sedentary in habit and exercised very little.

The older group claimed to have eaten more moderately and perhaps more sparingly of such cholesterol-containing foods as milk and eggs. Tobacco was used in greater quantity and by a greater number in the young group, the incidence of smokers being 93 per cent, which exceeds even the high incidence in the general population. The use of alcohol differs less widely for the two groups. There were slightly more total abstainers in the old group and few heavy drinkers in either group. With rare exceptions a history of serious infections (e.g., smallpox, typhoid fever and malaria) was much more common in the older group. A greater proportion of the older group were exemplary in their sleeping habits, and fewer of them were constipated. Nearly 70 per cent of the young group were robust in build or distinctly fat, whereas 83 per cent of the old folks were of average build or had been thin and lean for most of their lives. Nervous sensitivity and strain were frequently encountered in the young group but practically negligible in the older group.

We may therefore draw the following conclusions regarding coronary disease in the early decades of life. Men are overwhelmingly the victims. Hypertension as an important factor is predominant in women. A greater number of young patients than of patients in general may be expected to have hearts that are normal in size. There are fewer complications, and diabetes or evident peripheral vascular disease is uncommon. The duration of life for those who died and the life expectancy of the survivors is greater than for patients of all ages with coronary disease, but the susceptibility to sudden death is just as great. Inheritance and ancestral longevity are important factors in the early occurrence of coronary disease. Racial factors no doubt are also of importance in view of the high incidence of Jewish people in our series of 100 patients. Urban life, sedentary occupations and habits, possibly excesses of diet, the excessive use of tobacco, overweight and increased nervous sensitivity and strain all appear to be more predominant on the part of young patients with coronary disease than on

the part of persons who have achieved long life. Alcohol and serious infections do not seem to play an important rôle.

Although we still have much to learn about the underlying cause or causes of coronary disease, this study has afforded certain clues which offer a challenge to us and to those who follow to pursue this important and interesting subject to its final solution.

ABSTRACT OF DISCUSSION

DR H M MARVIN, New Haven, Conn. This excellent contribution is most important because it demonstrates clearly that coronary arterial disease in young people is not a rare condition. I have seen a moderate number of cases of coronary thrombosis in young people in their thirties and I think that without exception the physicians in charge had considered this diagnosis, only to reject it because of their belief that the patients were too young. Surely the time has come to emphasize that coronary arteriosclerosis may occur, literally, from infancy onward and is not particularly uncommon after the age of 30. Although it seems to me important that physicians should be familiar with this conception, I wish to comment briefly on the extraordinary infrequency of angina pectoris in young women. Coronary thrombosis is a relatively easy diagnosis to make, because it rests in most cases on demonstrable, abnormal, objective observations. The diagnosis of angina pectoris, on the contrary, rests exclusively on the history given by the patient, and a history suggestive of angina pectoris in young women should be received with great skepticism. As a matter of fact, one almost never receives from these young women a history that is wholly typical. They may have pain which is typical in its location, duration or radiation. If it is typical in these respects it is apt to occur in the absence of the usual provocative factors, namely, exertion and emotional excitement, or it may be unresponsive to glyceryl trinitrate or may be associated with dyspnea or with some other symptoms that are not a part of the recognized anginal syndrome. Drs Glendy, Levine and White have not had opportunity to refer to the recent work of Winternitz and his collaborators at New Haven. Those who have had the opportunity to hear Dr Winternitz's inspiring and convincing talk, and to see his amazing collection of photographs and drawings, will agree with me that he has demonstrated the extreme importance in this connection of hemorrhages in the vessel wall. I believe that this represents a vital contribution, probably the most important of recent years, to the pathogenesis of the condition.

DR W D STROUD, Philadelphia. While working with Sir James Mackenzie in St Andrews in 1920, I remember he used to say the age of 40 was the danger line. According to him, if a patient over 40 complains of symptoms suggesting cardiovascular disease, it is necessary for the physician to be absolutely positive nothing is wrong with the heart before he might assure the patient his symptoms were not cardiovascular. If a patient was under 40 years of age, the physician must be very sure there was some definite evidence of organic cardiovascular disease before he was justified in making a heart diagnosis. This paper is most timely, since Sir James's ideas have become popular. Now it is known a patient even in his twenties may have coronary disease. In the records of the five hospitals of which I am cardiologist, the youngest patient so far definitely diagnosed as having coronary thrombosis is a Jew of 28. Dr Wolferth tells me there has been no younger patient in the records of the University of Pennsylvania Hospital.

DR PAUL D WHITE, Boston. I want to say just a word about the electrocardiogram in these young people, something that we didn't have time to take up in detail. Dr Glendy and I had obtained twenty-nine cases from our own practice, Dr Levine helped us with twenty-three more, and the rest of the 100 cases were from scattered hospitals and physicians in Boston. To be on the safe side at the present time, we made the diagnosis of coronary disease in this group on the basis of clinical evidence in ninety-nine of the cases, that is, there was either certain coronary thrombosis or certain angina pectoris of coronary arteriosclerotic origin. Only one of the 100 cases was

diagnosed on the basis of the electrocardiogram alone. In other words, we erred on the safe side. I am perfectly certain that a good many other patients, especially young people, have only electrocardiographic evidence of coronary disease. As we study this problem further, we shall be making the diagnosis probably more often on the basis of the electrocardiogram alone. But we must be very cautious not to diagnose coronary disease on very slight changes in the electrocardiogram. There is now a danger of overdiagnosis if we aren't careful. We may swing so far in this direction that we may establish still more strongly the cardiac neurosis that is becoming common. Finally, a word about tobacco and coronary disease, a problem of ever current interest. Some years ago Dr Sharber and I reported a series of 750 patients with coronary disease and compared them with 750 control individuals of the same sex and age incidence without coronary disease. We found that there was very little difference in the use of tobacco or alcohol in these two groups. We did make the statement then, which we would confirm now, that occasional individuals have a definite sensitiveness to tobacco and, owing to increased blood pressure, increased heart rate, or other effects, have an increase of angina pectoris as a result of the overuse of tobacco. In this study of young persons we found a high incidence of the heavy use of tobacco, in contrast to the old persons. But I myself am already old enough to remember the days in Sunday school when I was told that tobacco was the devil's own invention and that to smoke cigarets was not only putting nails in my coffin but also sacrilegious. Nowadays the parsons of the country smoke about as much as anybody else, and therefore, naturally, tobacco is much more used at the present time by young people than by these older persons, with whom we have compared them, when they were young sixty or seventy years ago. We must bear that in mind before drawing any conclusions.

THE TREATMENT OF CORONARY SCLEROSIS AND ANGINA PECTORIS

BY PRODUCING A NEW BLOOD SUPPLY
TO THE HEART

HAROLD FEIL, M D

AND

CLAUDE S BECK, M D

CLEVELAND

This report concerns the results obtained in the treatment of coronary artery sclerosis and intractable angina by grafting vascularized tissues on the heart. Up to the present time we have done this operation on twenty-five patients. A sufficiently long interval of time has elapsed since operation so that we can begin to evaluate the clinical results of this operation.

The experimental basis for this operation has been published.¹ The anatomic arrangement of the heart and pericardium deserves some comment. Unlike any other organ, the heart is actually anchored in the body. It is anchored by the great veins and arteries and also by some fat, lymphatics and nerves that lie between these vessels. The fat at the base of the heart contains blood vessels that form anastomoses between the coronary arteries and other branches of the aorta, including the internal mammary, pericardial, phrenic, intercostal and esophageal.² These anastomoses were

demonstrated by the injection of india ink into the coronary arteries and by following the spread of the injection mass into the mediastinal tissues. Similar communications exist in the dog. In the absence of coronary disease these anastomoses are small, and it is doubtful whether they carry any significant quantity of blood. However, after the coronary arteries have been occluded by placing silver bands around the arteries, these anastomoses definitely increase in size and number, and it appears that these vessels may take on a real compensatory function.³ It was also shown that adhesions to the heart contain blood vessels that connect with the coronary arteries.⁴ India ink injected into the coronary arteries was traced through the adhesions into the pericardium, diaphragm and chest wall. These injection studies were carried out on human hearts that had adhesions from rheumatic heart disease. Similar anastomoses have been demonstrated by experimental studies. After the coronary arteries of a dog were occluded and grafts of skeletal muscle or fat were placed on the myocardium, anastomoses between the coronary arteries and the vessels of the grafts were demonstrated by injection studies.⁵

Do these arterial communications present in basilar fat and in parietal grafts or adhesions actually carry blood? Are they of any real functional value? In the presence of normally patent coronary arteries we do not believe that these anastomoses are of any functional significance. The blood vessels are anatomically present but do not function as anastomotic channels. In the presence of coronary arteries that are becoming occluded we believe that these anastomoses actually carry blood to the heart. That they carry blood was demonstrated by one or two observations made by Beck at operation on the human heart. In an operation for the resection of a compression scar a ribbon-like adhesion was found extending from the left ventricle to the thick pericardial scar. When the adhesion was cut, brisk bleeding occurred and each end of the transected tissue had to be ligated. The blood from the cardiac end of the adhesion came from the coronary arteries because there was no other possible source for it.

Another observation was made in the course of an operation in one of the cases reported in this paper. This patient had coronary artery sclerosis and at operation some mediastinal fat, the pericardium and the left ventricle were sealed together at the site of an infarct. An incision was made in the fat and while this was being done brisk bleeding was encountered. The fat was richly vascularized over the adherent area and the vessels carried blood. Are such extracoronary anastomoses of functional value in the presence of coronary artery occlusion? The clinical results after grafts are placed on the heart will help answer this question, as will also the data obtained by injection studies of the heart and grafts after death. Our report concerns the clinical results of the operation. The injection studies must await the future, because all the patients who withstood the operation and the immediate postoperative period are still living. Perhaps this fact in itself is of significance.

SELECTION OF PATIENTS FOR OPERATION

In selecting the patients for operation the requirements were (1) unequivocal evidence of coronary sclerosis, (2) inability to get along on medical treatment, drugs and rest with any degree of comfort and (3) absence of circulatory failure (with one exception). Hypertension was not regarded as a contraindication. Diabetes mellitus is no contraindication to operation, but it should be well controlled. The age of the patients ranged from 42 to 69 years. None had had recent infarcts. These requirements gave us a group of patients with advanced disease. They were poor risks for any kind of operation but we felt that we should take this group to determine the benefit, if any, that the operation offered. All presented the classic picture of Heberden's angina of effort and of emotion. Most of the patients were relieved by the nitrites, but this therapeutic test is not always diagnostic because of the side effects of the nitrites, headache and vertigo that are occasionally encountered.

SPECIAL STUDIES

Each patient was kept in the hospital for a period of from five to ten days, during which time detailed studies of the physical condition were carried out. These studies consisted of determinations of exercise tolerance, cardiac output, circulation time, roentgenograms of the legs and chest, kymographs of the heart, basal metabolism, blood dextrose, blood urea nitrogen, blood cholesterol, blood uric acid, phenolsulfonphthalein excretion, urea clearance, roentgenograms of the gallbladder and stomach when indicated, vital capacity, and blood Wassermann reaction. The tolerance for exercise was determined by means of the standard two step test. The patient was placed under basal conditions and the pulse rate, arterial pressure, respiratory rate and electrocardiogram were taken. In each instance the patient was free from pain before the test was started. Then the patient climbed the steps at the rate of from twelve to fifteen single trips per minute until a characteristic anginal attack occurred. The patient was then placed at rest and determinations of the pulse rate, arterial pressure and respiratory rate and an electrocardiogram were taken again and repeated after the pain subsided. Also the character of the pain was recorded. Similar exercise tolerance determinations were carried out on another day twenty minutes after the administration by mouth of a one-hundredth grain (0.0006 Gm.) tablet of glyceryl trinitrate. It was suggested by our colleague Dr. Roy Scott that the increase in the tolerance for exercise after glyceryl trinitrate as sometimes observed might give information concerning the degree of sclerosis present in the coronary arteries.

The minute volume output of the heart was measured by means of the Grollman method. The output determinations were within normal limits on each of the patients, and these studies will not be recorded. The arm to tongue circulation time was determined by the intravenous injection of dechlorin (sodium dehydrocholate). The circulation time is prolonged in cases of cardiac failure and we used this test as a further check on the condition of the circulation. The roentgenograms of the legs were taken to show the condition of the arteries. The renal function tests were made because of the possibility of uremia developing after operation in patients with severe arterial or arteriolar sclerosis. The results of these studies cannot be given in this paper and reference will be made only to the important deviations from normal.

⁵ Beck and Tichy.¹ Beck,¹ Mantz and Beck.³

THE BECK OPERATION

The operation consists of grafting vascularized fat and muscle on the heart. Skeletal muscle from the chest wall is readily available. Available fat lies in the mediastinum attached to the pericardium. Subcutaneous fat is also available and experimentally we used omentum brought up through an opening in the diaphragm. In the early operations costal cartilages on each side of the sternum were removed and a large graft of each pectoralis major muscle was applied to the right and left ventricles. The epicardium was removed so that the grafts came into contact with the coronary vessels. The pericardium was roughened so that the pericardial fat receiving its blood supply from extracoronary sources became attached to the myocardium. In the later operations the approach was made only from the left side of the sternum and a graft from the left pectoralis major muscle was used. Powdered beef bone was placed on the surface of the heart to produce a low grade inflammatory reaction between the grafts and the heart. The beneficial effect of procaine applied directly to the heart was worked out by our associate Dr. Frederick R. Mautz, and we now use procaine at operation.⁶ In the later cases the mediastinum was drained into the left pleural cavity. This is an important step in the operation and was described by our former associate Dr. R. A. Griswold.⁷ Quinidine was used as a routine before operation to reduce the irritability of the heart, and it is used after operation if necessary. We are prepared to defibrillate the ventricles should this complication occur at operation.⁸ The patient was placed in an oxygen tent as a routine after operation. The importance of these developments was indicated by the reduction in mortality. In the first twelve patients the mortality was 50 per cent. In the last nine patients the mortality was zero. Even though the patients are bad risks for any operation, we do not believe that the mortality in the future will be high for this operation on the heart.

REPORT OF CASES IN WHICH SURVIVAL OCCURRED

CASE 1—Arteriosclerotic heart disease and angina pectoris of nine years' duration, severe for five years, moderate generalized arteriosclerosis with hypertension, arterial pressure systolic 164, diastolic 92 mm. of mercury, moderate chronic pulmonary emphysema. A man, aged 48, Yugoslavian, a farmer, with gradually diminishing exercise tolerance, finally became incapacitated for any work because of pain. The exercise tolerance test, sixty trips on the steps, brought on precordial pain, fatigue and dyspnea. Operation was done Feb. 13, 1935. Four months later he began to do light work around the hospital as a gardener and made eighty-two trips on the steps without pain but stopped because of dyspnea. The patient has no symptoms at present and considers himself cured. We consider the result in this, the first patient ever to have this operation performed, to be excellent.

CASE 3—Arteriosclerotic heart disease and angina pectoris for five years, severe myocardia from total thyroidectomy in 1934. A business man aged 51, with severe angina of effort and of emotion became totally incapacitated. The exercise tolerance test, fifteen trips on the steps, produced complete exhaustion. Operation was done June 28, 1935. The amount of thyroid extract that the patient was able to take without

producing pain after operation was two or three times the amount taken before operation. Tolerance for exercise improved only slightly. The patient believes that the operation has lessened the pain a great deal but he remains weak. We believe that this patient has extensive fibrosis of the myocardium.

CASE 4—Arteriosclerotic heart disease, coronary sclerosis and angina pectoris of five years' duration, generalized arteriosclerosis, diabetes mellitus. A surgeon, aged 50, with angina of effort and emotion, was totally incapacitated in December 1932. Subtotal thyroidectomy was done in January 1933. He had a coronary thrombosis in February 1933. The patient had had diabetes mellitus since 1918, requiring insulin. He had had pain in the legs for three years on walking. A roentgenogram of the legs showed calcification of the vessels. The electrocardiogram showed a deep Q₁. Operation was done July 9, 1935. The angina has improved. He can stand emotional strain better. Exercise tolerance has increased from eighteen trips before operation to thirty-two trips at present. The patient is well satisfied with the result.

CASE 6—Arteriosclerotic heart disease and angina pectoris for two and one-half years, generalized arteriosclerosis and intermittent claudication. A machinist, aged 55, had the typical anginal syndrome brought on by exertion or emotion. The symptoms began in April 1933 after a severe attack of pain due to coronary thrombosis. He returned to work but tolerance for exercise progressively decreased, and in March 1935 he became totally incapacitated. The electrocardiograms showed a reversal of T in the chest lead and after exercise there were the typical changes seen in coronary arteriosclerosis. Operation was done August 31. The patient

returned to his former job five months after operation. Exercise tolerance increased from twenty-four trips before operation to thirty-seven trips after operation and the patient had to stop the step test not because of anginal pain, as before operation, but because of claudication. Because of these symptoms in his legs the patient changed his job in July 1936 to that of a storekeeper. The patient has no anginal pain, one year and eight months after operation. In this case of generalized arteriosclerosis and with a remote myocardial infarct, the result is excellent.

CASE 9—Arteriosclerotic heart disease and angina pectoris for three years and three months. A painter, aged 45, was forced to reduce his activities and finally was totally unable to work for two years and three months. Angina was produced by seventy trips on the steps and the electrocardiogram, which at rest was normal, showed characteristic changes in the ST interval. Glyceryl trinitrate increased the exercise tolerance to 102 trips. Operation was done Jan. 2, 1936. A year later he returned to his former work as a painter and

Chart 1 (case 11) —Studies obtained from step test before and after operation. The increase in trip tolerance was 303 per cent.

was able to do a good day's work with little discomfort. His ability to walk has not increased in proportion to his ability to take other exercise. He can take fifty-two trips on the steps without pain and without glyceryl trinitrate. It has been seventeen months since the operation and the patient has been restored to economic independence. On walking long distances he still has a recurrence of pain, but he has sufficient reserve to enable him to work a full day.

CASE 11—Arteriosclerotic heart disease and angina pectoris for sixteen months, probable coronary thrombosis of onset of illness. A tailor, aged 42, had angina of effort and emotion. He became totally incapacitated. Rest and drugs failed to give relief. Angina was produced by twenty-four trips on the steps. After glyceryl trinitrate he was able to make forty-six trips before anginal pain was felt. The conventional electrocardiogram was normal but T in the chest lead was reversed in direction. Operation was done Feb 22, 1936. The patient is now able to work. He can tolerate ninety-seven trips on the steps and stops because of dyspnea and not because of pain (chart 1). He is entirely comfortable.

CASE 13—Arteriosclerotic heart disease and angina pectoris for eleven years, probable attack of coronary thrombosis six years before admission and another attack seven months before admission, generalized arteriosclerosis and hypertension, early cardiac failure. A man, aged 58, an accountant, had dyspnea and edema of the ankles, which had appeared recently. The heart was enlarged. The electrocardiogram showed regular sinus rhythm, splintering of QRS in all leads and inversion of T in leads 1 and 2, T in the chest lead was reversed. The circulation time was twenty seconds. Because the patient was showing signs of heart failure, the usual operation was not done. May 25, 1936, one costal cartilage was removed, the pericardial cavity was opened and powdered beef bone was placed in the pericardial cavity. The congestive failure responded to treatment, but four months later the patient died. There was no autopsy.

Chart 2 (Case 20) — Studies obtained from step test before and after operation. The symbols have the same meaning as in chart 1. The increase in trip tolerance was 68 per cent.

have the complete operation carried out, he cannot be included in the analysis of results.

CASE 15—Arteriosclerotic heart disease and angina pectoris for five years. A salesman, aged 48, could not use nitrites because these drugs produced headache. He had restricted his activities to a minimum in order to prevent pain. The electrocardiogram showed inversion of T₂ and displacement of ST in the chest lead beyond the normal limit. The left ventricle was enlarged. Operation was done July 25, 1936. Some improvement followed and the patient returned to work. Exercise tolerance increased from forty-two trips over the steps, before operation, to sixty-one trips ten months later. Up to three months ago the improvement was only slight or moderate, but during the last three months the patient has shown marked improvement. He can do more work and the pain is considerably reduced.

CASE 17—Arteriosclerotic heart disease and angina pectoris in remission and secondary anemia. A machinist, aged 50, had a typical history of angina of effort for eighteen months. The basal metabolic rate was minus 30 and the patient took small doses of thyroid. The electrocardiogram revealed a left axis deviation and QRS of normal voltage. The T was almost iso-electric in all leads including the chest lead. Operation was done Nov 18, 1936. Congestive heart failure developed after operation and cleared up with appropriate treatment. Tolerance for exercise increased from thirty-six trips before operation to fifty trips after operation. The dose of thyroid has been increased. The patient definitely feels better than before operation.

CASE 18—Arteriosclerotic heart disease with angina pectoris of nine months' duration. A Green water, aged 48, had been incapacitated from work for six months. The T wave in lead 1 of the electrocardiogram was inverted. In the chest lead it was also reversed. The left ventricle was questionably enlarged. Operation was done Nov 21, 1936. Congestive heart failure developed after the operation. The patient has shown gradual but slow improvement. He is now working. He takes an occasional tablet of glyceryl trinitrate. Before operation he used five or six tablets daily. Circulation time was twenty-seven seconds and the heart was slightly enlarged to the left. The myocardium has probably been permanently damaged. It is significant that there is less pain.

CASE 19—Arteriosclerotic heart disease and angina pectoris of seventeen months' duration. A coal miner, aged 49, was totally incapacitated during the entire course of his illness. He had severe pain at rest, and morphine was given for the pain. Theophylline with ethylene diamine and glyceryl trinitrate gave no relief. The electrocardiogram showed alterations indicative of a remote posterior and basal infarct. Operation was done Dec 3, 1936. Marked improvement followed operation, but within the last two months there has been some recurrence of pain. The patient lives in another city and has not returned for study.

CASE 20—Arteriosclerotic heart disease and angina pectoris for one year. A salesman, aged 68, presented the typical symptoms of angina pectoris and became totally incapacitated. There was no episode suggestive of coronary thrombosis. The left ventricle was slightly enlarged. The arterial pressure was 150 systolic, 100 diastolic. Calcification of the peripheral arteries was present. The electrocardiogram showed regular sinus rhythm, left axis deviation Q₁ and Q₂, and a normal chest lead. After exercise the chest lead showed the ST portion sharply elevated (upright deflection positive in value). The circulation time was twenty-five seconds. Operation was done Dec 5, 1936. The patient became free from pain and discontinued all treatment. His activities are increased (chart 2). The result is excellent. He can walk with comfort and has started to work.

CASE 21—Arteriosclerotic heart disease and angina pectoris of five years' duration, mild diabetes mellitus. A clerk, aged 51, failed to benefit from medical treatment, paravertebral injection with alcohol failed to give relief and he became totally incapacitated from work. The left ventricle was slightly enlarged. The peripheral arteries were calcified. The electrocardiogram was normal at rest but after exercise showed definite alterations from normal. Operation was done Jan 30, 1937. The patient was much improved following operation. The pain has not completely disappeared but it is less severe. He has returned to work.

CASE 22—Arteriosclerotic heart disease and angina pectoris, thrombo angitis obliterans. A cook, aged 42, had angina of effort and emotion for five and one-half years and was incapacitated from his work for two years, he took morphine for the pain. The left foot was cool, and the arterial pulse was not palpable in the left leg. The electrocardiogram showed no significant changes before or after exercise. Operation was done Jan 30, 1936. He had several anginal attacks in the early postoperative period. Later he showed striking improvement. He is up and about and does not require medication. The interesting question arises whether the disease of the coronary arteries bears any relationship to the thrombo angitis obliterans of the leg.

CASE 23—Arteriosclerotic heart disease and angina pectoris of seven months' duration. A molder aged 49 had a typical history of angina of effort for seven months and had to give up work four months before admission. Medical care with a long rest in bed did not increase his tolerance for exercise. The anginal syndrome was produced by fifty three step trips and after glyceryl trinitrate he was able to make ninety trips. Electrocardiographic changes were present during the induced angina. The circulation time was twenty seconds. Operation was done March 6 1937. The patient states that he has felt better since the operation, but an exercise tolerance test two months after operation showed twenty-eight trips. It is too early to determine the result in this case.

CASE 24—Arteriosclerotic heart disease and angina pectoris of five years' duration A tailor, aged 50, in November 1933 and again in August 1936 had myocardial infarcts. They were anterior and apical, and posterior and basal. Invalidism followed the second attack and he was barely able to go to his shop. Slight exertion and emotional strain brought on pain. The left ventricle was slightly enlarged. The circulation time was twenty-three seconds. The venous pressure was 15 cm of physiologic solution of sodium chloride. The patient had extensive myocardial fibrosis and was a doubtful candidate for operation. Operation was done April 9, 1937. At the operation the heart beat was feeble and it was apparent that we were dealing with a seriously damaged muscle. The patient states that he has been greatly relieved from pain following the operation and he is returning to his shop. That the patient went through the operation and reports that he has obtained some relief from pain seems to be significant because we believe that he has a damaged myocardium. A longer period is necessary before we can make a final appraisal of the result in this case.

CASE 25—Arteriosclerotic heart disease and angina pectoris of nine years' duration A retired salesman, aged 52, had some attacks which were sufficiently severe to have been caused by coronary thrombosis. The conventional electrocardiogram was normal, but T in the chest lead was reversed in direction. The record taken during the induced anginal attack after exercise showed changes suggesting a posterior and basal infarct. Operation was done April 24, 1937. The patient states that there is some improvement, but it is too early to draw conclusions.

COMMENT

Thirteen patients have been observed for five months or longer after the operation. These patients may be divided into three groups, according to the results obtained. In the first group are patients in whom the result was better than we actually could expect to obtain—no pain, no drug therapy and exercise tolerance definitely increased. In this group are three patients, 1, 11 and 20. The second group contains cases with a result such as one might expect to obtain, considering the nature of the disease that is being treated. The patients in this group have pain, but it is less severe, they take occasional medication, the exercise tolerance has been increased. In this group are nine patients, 4, 6, 9, 15, 17, 18, 19, 21 and 22. In the third group is one patient, patient 3, who had some relief of pain and slight increase in exercise tolerance. There were no patients who were not improved by the operation.

Of the twenty-five patients operated on, sixteen are living and nine are dead. Autopsies were done on seven and in each case an advanced degree of coronary occlusion was found. In most cases extensive, permanent damage was present in the myocardium. Eight of the deaths occurred within one week of the operation. Only one patient died after discharge from the hospital and this patient did not have the usual operation done because he was in failure at the time. It is of interest to note that, while the mortality rate in the first twelve patients was 50 per cent, in the last thirteen patients the mortality was 15.4 per cent. The last nine consecutive patients have gone through the operation without mortality. We believe that we can expect a low mortality in the future.

CONCLUSION

We believe that the results obtained by this operation are encouraging. The beneficial effect of the operation may be explained by several possibilities. One of these is an actual increase in arterial blood to the myocardium. The second is a redistribution of blood

that passes through the coronary arteries. This is brought about by opening up intercoronary communications by surface trauma, grafts and powdered bone.

The opening of intercoronary communications could explain the early improvement noted by many of the patients. Almost without exception, the patients stated that they felt better eight or ten days after the operation than they did before the operation. This early improvement cannot be explained on the basis of blood from the grafts. A third possible factor to explain the improvement may be based on the interruption of nerve pathways from the heart. It is possible that the nerves lying beneath the epicardium are torn when the epicardium is removed.

We feel that thorough investigation should be given to the operation. The procedure is scientifically sound and its effectiveness will probably be increased by future study.

25 Prospect Avenue NW

ABSTRACT OF DISCUSSION

DR WALLACE M. YATER, Washington, D. C. I have followed the work of Drs. Feil and Beck and their associates with interest because of the importance of the problem involved and because of the steady progress made since they first began to use their method. I saw one of the patients operated on and observed several patients on whom the operation had been performed. Dr. Beck's method of encouraging the formation of a new blood supply to the myocardium should appeal to all as the most practical method of treatment so far devised for the treatment of coronary arterial sclerosis. Thus far Dr. Beck has used this method only in advanced cases of this disease. When the method comes to be applied to the less advanced cases, it will come to occupy its proper place in the treatment of coronary sclerosis. It is almost too much to expect a great deal from any form of treatment when the myocardium has become seriously impaired morphologically and functionally by extensive fibrosis. As has been demonstrated by Feil and Beck, even in such cases considerable improvement may result, but far greater benefit will undoubtedly occur in less advanced cases. Also, the mortality should be much less when the operation is used in such cases. In this connection the reduction in the magnitude of the operation as originally performed has made the procedure a much more practical one. The immediate relief of pain in some of the cases following operation is difficult to explain, since some time must be required for any significant amount of new blood vessels to invade the myocardium. However, the fact that the relief in these cases lasts for months and possibly years indicates that the effect is much more than psychologic. Strictly speaking, one would expect the improvement to be delayed for a while and then to be progressive up to a certain point. Whatever the mechanism of this immediate improvement, the fact remains that the patients are improved and remain so. Dr. Beck and his associates are very fair in hoping that other groups will now give this treatment a trial in order to help determine its exact value. In this regard I sincerely hope that only those well qualified and willing to devote much thought and time to the work will undertake it, since discredit may result if halfhearted and inefficient work is done, and years may elapse therefore before the operation finds its proper niche in our armamentarium of cardiac therapy. I wish to emphasize the point that the closest cooperation between the internist or cardiologist and the cardiac surgeon is most vital in this work, not only in the selection of cases but during the operation and in the postoperative care of patients.

DR HERMAN SHUDE, Cleveland. Fourteen months ago I never thought I would be able to face an audience. I am a patient of Dr. Feil's and I have today the advantage of talking as a patient and not as a physician. I do not agree with the last speaker who thinks that the operations in the future will be performed in the early stages of the disease. I think a

patient should get a chance to recover first, repair his myocardium and then, if the angina persists after a year or a year and a half, he has plenty of time to be operated on. In my work on peripheral vascular occlusions I have noticed that sclerotic occlusion was slow in developing. The collateral circulation developed beautifully. If I had a rapid embolus with a retrograde thrombus, the cardiac circulation did not develop properly and the results were not good. I made observations long before I had my coronary accident. Therefore, when the coronary accident took place in my own case I was not much discouraged. I wanted to be operated on but Dr Feil and Dr Beck had refused to comply with my wish. I went to Glenn Springs to get cured by the Neuheim baths. I was associated for eight months with nothing else but patients with coronary disease. Two thirds of the patients ought to go back to work after a proper abstinence from work and with proper optimism. I think that occupational therapy is exceptionally good. I believe in a moderate amount of exercise. I believe every muscle does much better if it exercises. A heart muscle is a muscle like any other muscle and it needs exercise, and surely one doesn't have to put one's patients flat on their backs and tell them there is no chance to recover. If the patient is told that he is going to go back to work and he has to go back to work, he will be better off. After having been a few weeks in a certain place where I was taken by my fellow in charge, I found out that by going back to Atlantic City and Cape May, associating with the young people, doing as McKenzie said, listening to a band of music and playing with the waves, I got along a lot better.

DR ROBERT L. LEVY, New York. Through the kindness of Dr Beck and Dr Feil I have had an opportunity of examining carefully two of their patients. One of the striking characteristics of both these men was an amazing optimism, verging on a state of euphoria. They were delighted with the results. Under the fluoroscope it was apparent that, in spite of the pectoral muscle transplants, there was very little diminution in the contractile power of the heart. The excursions appeared normal in extent, or nearly so. This procedure involves several basic principles. In the first place, it appears to be physiologically sound, there is a defect or an impairment in the circulation of an organ and, by surgical means, an attempt is made to increase that circulation. The procedure, in that respect, is in contrast to total thyroidectomy, which has always seemed to me to be physiologically unsound. In the second place, the operation on human beings has an abundant background of experimental work on animals. In the third place, as has already been mentioned, the study of this group of patients is an example of perfect cooperation between the medical man and the surgeon. I should like to ask two questions. First, what is the explanation for the almost immediate relief of discomfort? Why do these patients say, as did the two seen by me that they have had no recurrence of pain since the day of operation? Second, is there any way of knowing on the basis of animal experiments—for I believe there have been no postmortem studies in any human cases that have been followed for an appreciable length of time—what happens to the collaterals that are developed? When the transplanted pectoral muscle atrophies, do these collaterals disappear or is there reason for believing that they persist?

DR CLAUDE S. BECK, Cleveland. The results of this operation speak for themselves. Dr Feil and I have tried to maintain a detached point of view in evaluating the results, and we are interested only in scientific facts. The patients state that they are improved by the operation. Dr Feil and I agree with Dr Levy that some of the patients are really enthusiastic about the operation. The degree of enthusiasm troubles us occasionally because we are just as anxious as other physicians are to deal with facts rather than with emotional reactions. I should like to answer Dr Levy's question about the blood vessels in the grafts. What happens to the blood vessels after the muscle graft undergoes atrophy, and what happens to them after they have been established for a while. I cannot give a specific answer to this question. It is difficult to settle such problems, even though we have worked on this subject intensively for five years. There are still many things concerning this work that remain to be learned. In view of the fact that

we have done nine operations consecutively without a mortality, I feel that we can recommend the operation to patients with coronary disease. It might be of interest that we have done seventeen operations on the human heart without a fatality. Nine of these were for the grafting of a blood supply to the myocardium and eight of them were for the resection of compression scar on the heart. While this is not a record for future work in the surgery of the heart, nevertheless at the present time it means that there need not necessarily be a high mortality in operations on the heart.

DR HAROLD FEIL, Cleveland. Most of these patients have had very little pain at rest; only with excitement and exercise has pain occurred. Postoperatively they have been kept quiet for from six to eight weeks. Perhaps by that time, if Dr Beck's experimental data are applicable to man, some collateral circulation has developed. We are not misled by the fact that these patients say they feel well soon after the operation. As far as optimism is concerned, these patients all have had the accepted therapeutic procedures for angina pectoris. In fact, two patients had total thyroidectomies, one patient had a spontaneous myxedema, and one patient had a paravertebral alcohol injection. There were two patients taking morphine for the pain. Neither has taken morphine since the operation. One interesting point I did not mention was that postoperatively the electrocardiographic changes persist. The ST deviations following effort appear, even though there is no pain. This is due perhaps to the permanence of the myocardial scar, unaffected by the increased coronary circulation.

THEELIN THERAPY IN THE PSYCHOSES

EFFECT IN INVOLUTIONAL MELANCHOLIA AND AS
AN ADJUVANT IN OTHER MENTAL DISORDERS

C. C. AULT, M.D.

EMMETT F. HOCTOR, M.D.

FARMINGTON, MO.

AND

AUGUST A. WERNER, M.D.

ST. LOUIS

Since the experimental investigation of the effect of theelin (estrone) in involutional melancholia by Werner and his associates¹ in 1934, theelin has been administered to all patients received at Missouri State Hospital No. 4, Farmington, Mo., who had involutional melancholia, and to those whose mental condition was complicated by involutional psychoses. This procedure was not instituted with the hope that the substance would prove to be a panacea for all mental diseases but to alleviate the distressing subjective menopausal symptoms complicating other mental conditions. Frequently these symptoms obscure some other mental illness, making a diagnosis very difficult. In other words, we believe that we receive many patients suffering not only from some other definite psychosis but also from involutional melancholia.

Involutional melancholia per se is considered generally as a distinct clinical entity, and the controlled research previously done with theelin by our group strengthens this contention. Of those patients having involutional melancholia who were treated with theelin during the original experiment¹ at Missouri State Hospital No. 4 in 1934, three additional patients have shown marked improvement and have returned home.

1. Werner, A. A., Johns, G. A., Hoctor, F. F., Ault, C. C., Koller, L. H., and Weiss, M. W. Involutional Melancholia. *Isolated and Treatment*. J. A. M. A. 103: 1316 (July 7) 1934. Werner, A. A., Koller, L. H., Ault, C. C., and Hoctor, F. F. Involutional Melancholia. *Probable Etiology and Treatment*. Arch. Neurol. & Psychiat. 35: 106-1030 (May) 1936.

During the past year larger dosages of theelin have been administered, and we believe that the results obtained are more effective and rapid. During the first month of treatment, from 30,000 to 40,000 international units of theelin in oil was injected, and then the dosages were reduced to conform to the needs of the

TABLE 1—Results of Theelin Therapy in Involuntional Melancholia

Patient	Age	Duration of Treatment Weeks	Improvement	Period of Time Since Dismissal

13 E G	48	4	Moderate	In hospital
14 B F	40	8	Marked	Twenty two months

In the tables the term improvement is employed to mean the rehabilitation of the patient in her social life as to personality and capacity for work. All of these patients still in the hospital have been relieved of the distressing symptoms of hypo ovarianism.

individual patient. The amount used in the original experiments was approximately 5,000 international units in aqueous solution per month, and we now believe that this smaller dosage was responsible for the delayed response of the original group of patients as compared to those treated in this series. Formerly the average hospitalization was for a period of six months, but it is now rare to have a case of true involuntional melancholia require more than three months' hospitalization. Incidentally, there has been no evidence of injurious effects from the theelin used in any of the experiments.

The consensus is that involuntional melancholia constitutes between 3 and 4 per cent of all mental disease. In the mental hospitals of Missouri it has usually comprised from 2 to 4 per cent of first admissions. However, it is a well known fact that many women at the climacteric suffer from mild to marked mental aberrations with concomitant physical and mental handicaps, causing a prolonged convalescence of months to years, but for obvious reasons they are never institutionalized. Therefore, administration of estrogenic substances should prove a boon to these women, a relief to their families and an economic benefit to the nation.

ADDITIONAL INVOLUTIONAL PATIENTS TREATED

Since the original experimental work, fourteen additional patients with involuntional melancholia have received theelin therapy and eleven of these patients are socially adjusted at home, as is shown in table 1.

All patients have improved and one has been treated for only one month. Three patients showed such rapid improvement that it was impossible to persuade the relatives to let them remain longer, and two were taken out against advice a short time after admission, but most patients who have been dismissed early have continued theelin at home under medical supervision. Follow-up letters have been received at intervals in the majority of cases for from three to six months after dismissal, and only one patient has not continued to

improve and she was taken out against advice and undoubtedly the theelin was not continued. So far there has been only one readmission of this group and this patient remained out of the institution only nineteen days, having had treatment for four months. Since her return she has received six months' additional treatment with theelin and has shown marked improvement.

RESULTS OF THEELIN THERAPY IN SCHIZOPHRENIC PATIENTS DURING THE CLIMACTERIC

It is an established fact that involuntional melancholia complicates other types of psychoses. We have seen institutionalized patients become more disturbed with the advent of hypo-ovarianism and on the administration of theelin they have quieted down. As has been cited in a previous paper,² the stress and strain of the involuntional period evolve dormant potentialities of a schizoid personality into a typical case of schizophrenia, and this period of life has been shown to be the exciting factor in the early production of an organic psychosis.

Theelin therapy has been employed in the treatment of patients in the involuntional period who had definite symptoms of schizophrenia or cerebral sclerosis. The same dosage was employed as with involuntional melancholia, and there have been very few instances in which there has been no noticeable improvement in the mental disturbances. It is believed that in all cases the syndrome of hypo-ovarianism was relieved by the theelin, and in some instances, in which the medication was discontinued or interrupted early in the confusion of transferring the patient to another cottage or ward, the patients have asked for "the shots" to be continued because of the relief they experienced from them.

TABLE 2—Results of Theelin Therapy in Schizophrenic Patients During the Climacteric

Patient	Age	Improvement of Psychosis	Status on Discharge	Time in Months Since Discharge
1 S S	37	Marked	Improved	21
2 M B	44	Marked	Improved	6
3 A Z	44	Marked	Improved	20
4 B Z	42	Marked	Improved	10
5 L H	41	None	Stationary	13
6 L B	46	Marked	In hospital	
7 E P	45	Moderate	In hospital	
8 K N	51	Slight	In hospital	
9 C O	44	Marked	Improved	0
10 L W	42	Slight	In hospital	
11 M W	46	Marked	Improved	6
12 R A	52	Marked	Improved	10
13 M J	43	Slight	In hospital	
14 L S	45	Slight	In hospital	
15 F G	41	Moderate	In hospital	
16 M G	35	Marked	Improved	15
17 E H	45	Moderate	In hospital	
18 M M	41	Slight	In hospital	
19 C H	23	Moderate	Improved	2
20 J P	52	Marked	Improved	8
21 E W	39	Marked	Improved	24
22 E K	45	None	In hospital	

Naturally the length of treatment has varied for a number of reasons, but in those who showed no noticeable remission of their psychotic episode after six months the therapy was discontinued, and it has never been continued longer than one year in a single case.

In table 2 the results of the therapy in twenty-two schizophrenic patients have been tabulated. The average age was 44 years and the means were 52 and 28

years, the latter patient being the only one suffering from artificial menopause (surgical). The ten patients who made social recoveries were hospitalized for an average period of six months.

RESULTS OF THEELIN THERAPY IN CEREBRAL ARTERIOSCLEROSIS IN THE CLIMACTERIC

Table 3 shows the results of treatment in the organic cases, and naturally these are not very impressive, but the tabulations in both the functional and the organic cases do not depict the true state of affairs. Even the two patients in each group who showed no mental improvement became much more comfortable in the hospital, and the majority became so much better adjusted to hospitalization that they could be moved from the wards for disturbed patients to quiet cottages.

Patient 6 in the schizophrenic group is to be paroled soon, and those who have shown moderate improvement in both groups have spent variable periods of time on parole at home, usually from three to four months.

Other psychoses, such as manic-depressive, psychoneurosis and psychosis with other somatic diseases (thyrotoxicosis, cardiorenal disease and the like) with definite symptoms of involutional melancholia, have been aided in a more rapid improvement or recovery as the case may be, by the administration of theelin. Six manic-depressive patients have recovered with an aver-

TABLE 3—Results of Theelin Therapy in Cerebral Arteriosclerosis in the Climacteric

Patient	Age	Improvement of Psychosis	Status on Discharge	Time in Months Since Discharge

13 L F	50	Marked	Improved	31
14 A B	50	Slight	Stationary	25
15 C S	47	Slight	In hospital	

age hospitalization of four months. Only the patients with cardiorenal disease did not recover and they were moderately improved, but all were relieved of the intense depression and nihilistic trends.

CONCLUSIONS

1 For all practical purposes theelin seems to be specific in involutional melancholia, the apparent recovery rate being 92 per cent in our series of cases.

2 Massive doses of from 30,000 to 40,000 international units for the first month of treatment accelerate the recovery rate in involutional melancholia, the hospitalization being reduced to an average period of three months.

3 Theelin is indicated for any woman during the climacteric having disturbing mental aberrations, whether mild or severe.

4 Theelin therapy is efficacious in relieving distressing symptoms of the climacteric in other types of psychoses, many patients being improved to the extent of recovery.

CONGENITAL OCCLUSION OF THE CHOANA

CARL M. ANDERSON, M.D.
ROCHESTER, MINN.

Congenital occlusion of the choana is a comparatively rare developmental anomaly, approximately only 160 cases having been reported since 1830. Only six cases have been seen in the Section on Rhinology of the Mayo Clinic since 1907, and in only one of these cases was the occlusion bilateral.

It is surprising to note that all the patients were in fairly good health, inability to breathe properly through the nose apparently not having been a serious handicap to their normal development. There was no history indicating any hereditary tendency toward development of the condition, and there were no other apparent deformities or asymmetries. None of the patients seen at the clinic had any disease of the ears. Removal of the obstruction in each case restored normal function.

EMBRYOLOGY

The olfactory epithelium arises in embryos of about 4 mm as paired ectodermal thickenings, olfactory placodes, on the ventrolateral sides of the head. Specimens 8 mm long (middle of the sixth week) show the margins of each placode elevated about a central pit. Around these olfactory fossae the nose develops. Each first branchial arch forks into a maxillary and mandibular process. Dorsal to the mouth is the fronto-nasal process of the head. Laterally on the maxillary processes and ventral to the mouth are the mandibular processes. With the appearance of the nasal pits the lower part of the frontonasal process necessarily is subdivided on each side into a lateral and a median nasal process.

The nasal depressions are at first grooves, each bounded mesially by the median nasal processes and laterally by the lateral nasal and maxillary processes. These nasal grooves connect temporarily with the oral cavity. As development proceeds, fusion of the maxillary processes with the median nasal processes converts the nasal grooves into blind pits, opening by primitive anterior nares and separated from the mouth by ectodermal plates. Later, the union of the median nasal process which forms the septum with the lateral nasal process reduces the size of the external nares. The epithelial plates, which separate the nasal fossae from the primitive mouth cavity, become thin membranous structures as the nasal cavities extend backward and by rupturing during the seventh week produce the primitive choana. The front part of the plate is invaded by mesoderm, thereby forming the primitive palate, which differentiates into the lip and the premaxillary palate. The nasal fossa now opens externally through the external nares and communicates internally with the mouth through the primitive choana. As the ventral border of the septum fuses with the palate, it separates the two passages completely. The permanent nasal passages thus consist of the original nasal fossae plus a portion of the primitive mouth cavity which has been appropriated secondarily by the development of the palate.

About this time the superior maxillary process, which is an offshoot of the process of the mandibular arch,

From the Division of Otolaryngology and Rhinology, the Mayo Clinic. Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

assumes its rôle in the formation of the permanent mouth and nasal cavities. The palatal processes of the maxilla grow medially and slightly forward concurrently with the downward and backward growth of the nasal septum, which is thinned out in the process. The growth of the palatal portion of the maxillary processes continues until they meet in the midline, where they fuse firmly with each other, the vomer posteriorly and the septum anteriorly. This fusion completes the formation of the palate and the floor of the nasal cavities.

If one keeps in mind the fact that the floor of the rudimentary nasal cavities was formed by the premaxilla and that the next stage of growth was by backward displacement of the nasal septum, leaving the floor deficient and in contact with the tongue, it becomes apparent that the primitive choanae are not the same structures as the fully formed choanae.

Normally, the choanae are formed by the body of the sphenoid, medial plates of the pterygoid processes, posterior border of the septum, and fusion of the hard and soft palate. The most popular theory as to the cause of congenital absence of the choana appears to be (1) persistence of the nasobuccal membrane, (2) persistence of the buccopharyngeal membrane and (3) overgrowth of the vertical and horizontal processes of the maxillae. When the atresia is membranous, the probability is that it is caused by persistence of the nasobuccal membrane. When the occlusion is bony, there seems to be some uncertainty as to its origin. The bone forming the obstruction has been shown to be formed from cartilage, which would indicate that it probably was formed from persistence of the buccopharyngeal membrane.

Should primitive choanae dorsal to the primitive palate not form during the process of development, the epithelial lining of the primitive nasal fossa and the epithelial lining of the primitive oral cavity would remain intact, each separated from the other by the thinned-out mesenchymal floor of the early nasal fossae. The continued dorsal growth of the nasal fossae into the mesenchymal mass of the nasofrontal process would ultimately, in cases of maximal growth, lead to a condition in which the epithelium of the nasal fossae would come in contact with the epithelium of the foregut, that is, the nasal portion of the pharynx with a variable amount of mesenchymal tissue between the epithelial surfaces. This would result in blind-ending nasal fossae dorsally. If the amount of mesenchyma between the pharyngeal and the nasal epithelium should remain thick, an osseous atresia would ultimately be formed.

SYMPTOMS

The symptoms of choanal obstruction are quite apparent and consist of inability to breathe through one or both nostrils and the accumulation of thick mucus in the occluded nostril, which can be removed only by wiping or stooping forward. When only one nostril is obstructed, the symptoms are of course much milder. In the new-born there is an inability to nurse, and a tendency to suffocation and cyanosis, especially during the act of swallowing, during sleep and when the mouth is closed, which symptoms can easily be confused with the syndrome caused by enlargement of the thymus.

Several writers have called attention to the fact that congenital occlusion of the choana probably is an unrecognized cause of infant mortality much more often than the literature on the subject would indicate.

In nearly all the cases of choanal occlusion reported patients have survived the first few years of life, so there can be little doubt that if the condition was recognized at birth or during the first few days of life, many more cases would have been reported. In the first case of choanal occlusion to be found in the literature, reported by Otto in 1830, the condition was discovered at necropsy. In Stewart's¹ report of the cases of two sisters with congenital bilateral atresia he called attention to one other member of the family who had died in early infancy probably because the condition was not recognized. A few cases have been reported when the atresia was discovered early and the infant's life saved by relief of the obstruction.

REVIEW OF THE LITERATURE

In 1859 Luschka² reported the case of a 7 year old boy in good health who had bilateral bony occlusion and complete obstruction of both choanae. At birth there had been great difficulty in maintaining his life, he had not been able to nurse and his mouth had to be kept open to permit breathing. He was sent to Carl Emmert for surgical treatment, as the latter had had some previous experience with the condition, having reported a case of choanal occlusion in 1851.

Ronaldson³ in 1880 reported a case of bilateral membranous choanal occlusion which he had encountered in his obstetric practice. After delivery he noted that, on attempting to inspire, the child's lungs were not inflated, when the child was held up, however, the mouth was opened and free respiration took place. After removing a mucous plug on each side, he discovered a dense membrane completely closing the choanae, unfortunately he delayed operation and the child died an hour later. He stated in his discussion that breaking down of the membranes should not be delayed, and he suggested the alternative of a gag, to prevent closure of the mouth, or tracheotomy.

Hubbell⁴ in 1886 reviewed all published reports of cases up to that time, totaling seventeen in all. Of these, occlusion was complete in both nostrils in eight cases, complete in the right nostril in four, and complete in the left nostril in three, occlusion was incomplete in both nostrils in one case and in the left nostril in one case. The occlusion was bony in twelve cases, membranous in five. Hubbell found the first case reported, which has been mentioned previously, to be that reported by Adolph Wilhelm Otto of Breslau in 1830, and he stated that Otto had implied that other such cases had been seen previously. According to Hubbell's review, Carl Emmert was the first to report a case in which operation was performed for relief of the condition. Hubbell reported a case of his own, in which the patient was operated on with a hand drill, 13 mm in diameter, and obtained complete relief, the opening later contracted, however, making a secondary operation necessary, at which time tubes were placed in the nose and left for seven weeks, with eventual complete and permanent relief. Hubbell did not mention any deformity of the hard palate but called attention to the fact that there had never been any disturbance in hearing and that the eustachian tubes, tympanic cavities and tympanic membranes were normal in all.

respects although the conditions of Toynbee's experiment were constantly present

In explanation of this phenomenon, I would suggest that in the case of an individual with congenital occlusion the act of swallowing must be done without the aid of nasal respiration, and that it is therefore through necessity and early training accomplished in somewhat modified form from the normal, whereas in Toynbee's experiment the nostrils and mouth are tightly closed during the act of swallowing

Clark⁵ called attention to the fact that, owing to the rarity of congenital choanal occlusion, it might not be of much practical interest to the physician but that there was no doubt that infants might die from want of knowledge on the part of the family doctor, obstetrician or pediatrician of the possibility of the existence of such an abnormality. Clark could find in the literature only three cases of complete choanal occlusion from 1886, the date of Hubbell's article reporting seventeen cases, up to 1897, he added one of his own, making twenty-one in all. He did not include any cases in which there was only partial occlusion in one or both nostrils but referred only to complete bilateral occlusion. Operation in his case was by means of an electric trephine, making an opening 11 by 13 mm in each nostril. The results ten years after operation were good.

Fraser⁶ in 1910 reported one case in which he was able to secure a specimen at postmortem examination. The patient had died from meningitis secondary to chronic otitis media in the left ear. The right choana was occluded. The right drum was normal and there had been normal hearing on the right side. The nasal septum was deviated to the right. The sinuses were clear. Fraser's specimen revealed that the two antrums were of some size, and he called attention to the fact that this was against the theory of Freis that development of the nasal accessory sinuses results from the presence of air currents in the nose. Fraser stated: "On microscopic examination the nasal mucosa of the left olfactory region showed normal appearance, whereas that of the right olfactory region showed almost complete desquamation of the surface epithelium and fibrous thickening of the submucous tissue. There was also on the right side considerable small cell infiltration especially of the deeper layers of the submucosa. The mucous membrane of both maxillary antrums was normal." In a review of the literature Fraser found a report of 115 cases of choanal occlusion, but some of these cases were not sufficiently described. Out of the 108 cases that were described, in forty the occlusion was bilateral, in thirty-six on the right side, and in thirty-two on the left side. The occlusion was bony in eighty-nine cases, membranous in ten. In nine cases the type of obstruction was not stated.

In many cases of choanal atresia there are changes in the middle ear. In Fraser's case, for example, the ear on the obstructed side was normal, whereas that on the other side was the seat of chronic otitis media.

White⁷ stated in 1919 that the main difficulty in operations for bony occlusion of the posterior nares has been that of obtaining a permanent opening. He reported two cases, one of a man, aged 50, with obstruction on the right side, the other of a girl, aged 18 years,

with bilateral bony occlusion but normal drum membranes. He stated that approximately 150 cases had been reported up to 1919.

In 1921 Kirby⁸ reported two cases of choanal occlusion, in one of which he made the diagnosis while examining the nose with a probe. Submucous resection was performed first and the bony obstruction was then removed through this route. After removal of the obstruction Kirby made a flap from the membrane at the base of the pharyngeal side of the choana, thus covering a portion of the operative surface. Rubber tubes were placed to maintain the opening. He noted that the ear drum was retracted and that there was also a band of tissue covering the orifice of the eustachian tube. A test of hearing revealed catarrhal deafness, the degree of which was not stated. No mention was made of the condition of the hearing in the second case, the same surgical procedure being instituted as in the first case.

Out of 27,863 patients with diseases of the nose and paranasal sinuses who registered in the ear, nose and throat department of the Royal Infirmary of Edinburgh, under A. Logan Turner and J. S. Fraser, only six cases of unilateral atresia of the choana were found. These were reported by Stewart⁹ in 1931 in connection with two cases of complete bilateral atresia which came to his attention at the Deaconess Hospital. Both patients, who were sisters, were operated on with good results. One brother had died in infancy apparently from unrecognized bilateral complete choanal obstruction. Stewart called attention to the fact that growth of the palatal processes of the maxilla medialis is apparently not influenced by either the breaking down or retention of the nasobuccal membrane. Cleft palate results when the nasobuccal membrane does break down. Apparently no atresia of the choana results when the hard palate does not consist entirely of bone. Stewart believed that more cases would be found if infants thus afflicted lived beyond the first day or two of life.

Roth and Geiger¹⁰ in 1926 reported one case of bony occlusion of the right choana.

Grove¹¹ reported one case of complete bony occlusion on the right side. The obstructing tissue was punctured with a chisel and the edges were bitten away with a sphenoid rongeur until the opening measured 1 cm by 1.5 cm. A rubber tube was left in place for five days and was then changed at intervals of three or four days thereafter for two weeks. The ultimate result was very good.

Stinson¹² reported two cases in 1932, one of bilateral and one of unilateral atresia. In one of his cases there was marked asymmetry of the face, with encroachment of the lateral wall of the nasopharynx on the choana. At operation, part of the vomer was removed with the choanal obstruction, thus draining the right nostril into the left side. There was no difficulty with healing.

Culver¹³ reviewed one case in which the patient was operated on in 1918 at the age of 2 years and 8 months. The case was reported at the American Laryngological,

Rhinological and Otological Society in 1920. A portion of the posterior edge of the septum was removed along with the obstruction in the choanae. The obstruction had been noted at birth, but nothing was done to correct it until the child was past $2\frac{1}{2}$ years old. At the age of 21 the patient was breathing normally but had not developed normally, either physically or mentally.

Culver¹² added another case, of an infant 6 days old, seen in 1934. The patient was suffering from typical cyclic dyspnea, was unable to nurse, and had to be fed with a medicine dropper. The diagnosis was made by air pressure from a rubber bulb and by introduction of a guarded applicator. Nineteen days after birth an operation was performed to relieve the obstruction. A flap of mucous membrane was turned back laterally and a portion of the mucous membrane on the septum was retracted forward. A protector was placed in the nasopharynx. With a small Alexander mastoid gouge the bony obstruction was perforated and reamed out to normal size. A small portion of the septum was removed. Rubber tubes were placed in the nose, extended through the choanae and left in place several days.

REPORT OF CASES

CASE 1—A man, aged 35, came to the clinic with the history of never having been able to breathe through the left side of his nose. Examination revealed a wide deflection of the septum to the left with a great deal of mucus back of this deflection. Jan 19, 1920, with the patient under local anesthesia, submucous resection was performed. When the deflection was removed it was discovered that there was a complete bony occlusion of the choana on the left side. This was removed from between the septal membranes, and the membranes over the posterior nares were cut away with forceps. A pack was placed in the left side and brought out through the right side. There was complete relief of symptoms and the patient has remained well since.

CASE 2—A boy, aged 14 months, was brought to the clinic because of inability to breathe through his left nostril. Examination revealed that the left side of his nose was filled with mucus, the membranes were boggy and dark gray. The adenoid pad and the occluding membrane had been removed previously elsewhere. The patient was operated on again at the clinic Oct 21, 1930, the membranous occlusion being completely removed with biting forceps. He was completely relieved and has remained well since.

CASE 3—A girl, aged 11 years, was unable to breathe through her nose. She had undergone adenoidectomy when only 11 months old and was operated on again for the same condition at the age of 3 years. Four years later tonsillectomy and adenoidectomy were performed, but without relief. The patient was subsequently treated for sinus infection, and attending physicians at that time stated that she had a bony growth in her nose. Examination at the clinic revealed membrano-osseous occlusion of both choanae, with a small opening on each side near the top. June 8, 1927, with the patient under oil ether anesthesia, the obstruction was removed by means of chisel, forceps and bur. A large catheter was placed on each side and left in place for about ten days. The result was very good, the patient having had no trouble since.

CASE 4—A boy, aged 14 years, complained of inability to breathe through the right side of his nose. On examination the anterior end of the right inferior turbinate was found to be very large. Aug 18, 1930 with the patient under local anesthesia, the enlargement of the turbinate was removed. The nostril was found to be filled with mucus and, when this was removed, complete bony occlusion was discovered. There was also a large bony spur into the nostril from the sphenoid. The spur and bony occlusion were removed with a chisel. A specimen of the bony occlusion measured about 5 mm in thickness. The patient has had no trouble with his breathing since that time.

CASE 5—A boy, aged 8 years, was brought to the clinic with the history of having been unable to breathe through his nose since birth. The physician in attendance at birth stated that he had opened the choana during the first week of life but the obstruction reformed. The patient's general health was good. July 17, 1935 with the patient under intratracheal gas anesthesia, the tonsils and adenoids were removed and the obstructing membrane was removed at the same time with biting forceps. A large tube was placed in the nose. Recovery was complete and permanent.

CASE 6—A woman, aged 33, came to the clinic stating that since birth she had been unable to breathe through the right side of her nose. At the age of 14 years, turbinectomy had been performed without relief. On examination at the clinic the right nostril was found to be filled with thick mucus. The membranes were congested and dark gray, and appeared to be inactive and boggy. Owing to previous removal of the turbinate, a clear view of the posterior end of the nostril was obtained after removal of the accumulated mucus and it was apparent at once that there was complete occlusion of the choana. A probe revealed dense bone throughout. May 28, 1936, with the patient under intratracheal gas anesthesia, the thick bony obstruction was perforated with a trephine. Through this opening a modified Kerrison punch was passed and the edges were taken down until all were on a level with the surrounding structures, after which all roughness of the edges was smoothed off with a fine rasp. No packing or tubes were used. After four days the nostril was cleaned daily with a suction cannula over a period of one week. The patient was dismissed on the tenth day and has reported recently that she has had no trouble since dismissal.

SUMMARY

While congenital obstruction of the choana is a rare condition, it appears that more cases would be found if the condition were recognized more often in infants with nasal obstruction, particularly when the nostrils are filled with glairy mucus. The symptoms of choanal occlusion may be confused with those resulting from an enlarged thymus.

It is interesting to note that an individual may grow to full maturity in relatively good health without a nose or with only half a nose, respiratory function being taken over by the mouth. While some patients with atresia of the choana have some ear trouble, a much larger number have no symptoms referable to the ears. In one case of unilateral obstruction which came to necropsy the paranasal sinuses were found to be equally well developed on the two sides. It is relatively infrequent to find other developmental anomalies in cases of choanal atresia. There is some speech defect in nearly all cases, particularly when both sides are occluded. When the speech defect persists after relief of the nasal obstruction, it is probably due to habits of speech formed early in life.

New¹³ has stated that when cleft palates are repaired before the child learns to talk there is usually no speech defect, whereas if they are repaired after the habits of speech are formed there is great difficulty in overcoming such speech defects. It would seem reasonable to assume that this applies as well to speech defects resulting from congenital occlusion of the choana.

In cases in which there is obstruction to breathing through one or both nostrils and a considerable amount of thick mucus is present, one should suspect occlusion of the choana. The obstruction can be permanently relieved by surgical means. Various surgical procedures are described, but the type of operation used should be determined by the needs of the particular case under consideration.

ABSTRACTS OF DISCUSSION

DR J P SCHAEFFER, Philadelphia I have been requested to speak on the embryology of this defect. What especially concerns us in the present connection is the congenital atresia of the choanae in otherwise essentially normal oral, nasal and pharyngeal cavities, albeit that atresia of the choanae may be accompanied by other facial defects and arrests. These atresias are amenable to treatment resulting in the establishment of normal or, at least, satisfactory function. Although there may be other ontogenic and developmental factors underlying this type of atresia of the choanae, my studies both of the defect and of the embryology of the nose and palate lead me to believe that the explanation of the anomalous anatomy under consideration is found in (a) the abnormal behavior of the bucco-nasal membranes and the primitive choanae, (b) an inadequate absorption of the floor of the secondary nasal fossae dorsal to the position of the primitive choanae, and (c) the degree of dorsal growth of the secondary nasal fossae. At an early time in the human embryo the nasal fossae are two blindly ending, epithelially lined pouches lodged in the mesenchymal tissue over the primitive oral cavity. The growth of the nasal sacs normally results in a thinning of the floor of the early nasal fossae, so that ultimately the nasal epithelium and the oral epithelium abut dorsad to what later becomes the intermaxillary bone, thus establishing the thin bucconasal membranes. The latter rupture about the thirty-sixth day of embryonic life. This results in the formation of the primitive choanae, the communicating apertures between the primitive nasal fossae and the primitive mouth cavity. Normally the early primary nasal pits expand dorsad over the roof of the mouth behind the primitive choanae, and at the same time there begins an absorption from before back of the floor of the secondary nasal fossae. Concurrently with these changes the palatal shelves of the maxillary processes begin to appear, first directed vertically and extended toward the mouth cavity, later becoming rotated from the vertical and sagittal plane to a horizontal plane. Following this initial stage, the palatal shelves grow medially and fuse over the tongue in the midsagittal plane. Important in this connection is the fact that the rotation, growth and fusion of the palatal shelves separate the oral cavity from the secondary nasal fossae, and in doing so a goodly portion of the oral cavity is carried to the side of and incorporated with the hindmost portions of the nasal fossae. The expansion of the primitive nasal fossae dorsad into the mesenchyme, the establishment of the primitive choanae by the rupture of the bucconasal membranes, the growth, rotation and fusion of the palatal shelves, and the inclusion on the nasal side of a portion of the mouth cavity lead to an elongation of the nasal fossae anteroposteriorly and the establishment of the definitive choanae at the juncture between the now elongated nasal fossae and the nasal portion of the pharynx.

DR HARRY P SCHENCK, Philadelphia No one sees many of these patients. The only one I was concerned with, an infant of 6 months, had unilateral choanal obstruction and atresia of the external auditory canal on that side. The choanal obstruction was satisfactorily correlated but the atresia of the external auditory canal was not, although roentgenograms showed apparently normal ossicles in the middle ear. The most important feature of Dr Anderson's presentation is the attempt to bring to the attention of obstetricians and pediatricians the fact that immediate treatment of complete bilateral occlusion of the choanae in the new-born is a life saving measure. It is of some interest that of six patients in Dr Anderson's series four were males and two females. Fraser and Kahler stated that females were especially affected. Statistics in these rare conditions are always dangerous. It appears from this series that study of a sufficient number of cases will reveal that sex is not a factor in the incidence. I was interested in Dr Schaeffer's stating that heredity was not a factor and I am certain that he is correct. I have always been influenced by Lang's report of five members of a single family who had unilateral occlusion of the choana and in each instance the occlusion was on the same side. Satisfactory results followed Dr Anderson's operative intervention in every case. Unfortunately, this is not always the case. The membranous obstructions probably cause more difficulty than the bony ones. It seems that cauterization is useful if followed by dilation with

rubber bougies. In the bony obstructions the excision cannot be too widely made. An attempt is made to render the caliber that of the nasal fossa, because the thing that is feared is postoperative cicatrization. If epidermization does not follow promptly, this is a serious factor to contend with.

DR R C GROVE, New York Dr Anderson has rendered otolaryngologists a service in presenting so clearly the subject of congenital atresia of the choanae. One is apt to think too little about embryology in routine clinical work. The portion of his paper dealing with the embryologic development of the nose is instructive. The important question to decide is: Are we failing to diagnose this condition as often as it occurs? Dr Anderson has wisely suggested that some of the deaths in the first few hours or days after birth may be due to bilateral choanal atresia. We all know that removing the adenoids in every child with difficulty in breathing through the nose without a proper nasal examination is to be condemned. I believe that a cotton-tipped probe can be passed through each nostril without causing much distress to the patient. All older children and adults should be examined with the nasopharyngoscope. Dr Anderson's paper impressed me with the number of cases in which submucous resection, trimming of the turbinates and even removal of tonsils and adenoids was done without diagnosis of the atresia until the time of operation or later. Possibly because of its infrequency one does not think of it. Dr Anderson reports six cases at the Mayo Clinic in thirty years, and Logan Turner six cases in the Royal Infirmary of Edinburgh in twenty years. I have seen two cases during the past ten years. Both of these were seen in my allergic work, a point which I would emphasize as the patients complained of sneezing and of a mucous discharge from the affected nostril. Both were young girls in their twenties and the interesting feature in the first case was that she had never noticed that she did not breathe through the one nostril. She had had her tonsils removed in one clinic and a second check up in another without the condition being diagnosed. Both patients had perfectly normal hearing on the side of the atresia, which makes one wonder about the necessity of submucous resection in so many cases of deafness. Treatment in most cases of choanal atresia is simple, as Dr Anderson has pointed out. I think the important and necessary procedure is to make a sufficiently large operative opening and to maintain the patency of the operative area during the first few weeks of convalescence.

DR GORDON B NEW, Rochester, Minn. I might say a word about these children particularly the ones that die shortly after birth. Death is due to the fact that they have trouble breathing on account of their tongue sucking back against the pharynx, resulting from the complete obstruction of the nose. In two cases I have been able to pass a catheter into the hypopharynx just back of the tongue holding the tongue forward and thus giving an airway. Immediately one will find that these children who were unable to breathe and unable to eat except with difficulty, are able to breathe quietly by means of the airway. In both these cases I replaced this catheter with a piece of curved celluloid about the size of a slate pencil with a cross piece at the mesial end, which was outside the mouth and was attached to the cheeks with silk and adhesive plaster. The child wore this piece of celluloid all the time and was able to sleep normally, to take the feeding bottle with this apparatus in place, and it really gave the child no inconvenience. Later, as the child got older, it was possible to remove this celluloid piece permanently.

DR C M ANDERSON, Rochester, Minn. I should like to call attention again to the fact that congenital occlusion may in some instances be a cause of infant mortality when it is bilateral. There may be some speech defect, and there usually is if the child learns to talk before the obstruction is corrected. Dr New has stated in relation to cleft palates that, if the operation is performed and the defect corrected before the child learns to speak there is usually no speech defect. I believe that the speech defect in these cases is due to inability to breathe through the nose. Operations in these cases should be suited to the individual. I do not believe there is any set rule for operation. All of the six operations performed at The Mayo Clinic were in some respect different.

TRYPARSAMIDE THERAPY OF NEURO-
SYPHILIS AND ATROPHY OF
THE OPTIC NERVE

LEO L. MAYER, MD

CHICAGO

It has been fifteen years since the first injection of tryparsamide was given for syphilis of the central nervous system¹. The frequency of involvement of the optic nerve in neurosyphilis prompted an early report on the visual disturbances produced by tryparsamide². It seems fitting at this time to reconsider and reflect on the conclusions of these early reports by means of a study covering a ten year period, during which time a relatively large and varied group of patients were observed as to the end results obtained. Three clinics in the Chicago area were chosen for this report: the Mandel Clinic of the Michael Reese Hospital, the Eye Clinic of the Northwestern University Medical School and the Syphilis Department of the Public Health Institute. An attempt was made to review the progress of every patient treated with tryparsamide after it became available. For the past seven years I myself have been seeing such patients in each of these institutions. Obviously, not all patients were active in the clinics in June 1936, the limit of the time for the check-up used in this report, and in addition certain patients could not be traced, others had died and some had left the vicinity. Figures as to these difficulties will be given later.

Five years ago Dr R. D. Smith and I presented a report on eighty-seven patients receiving tryparsamide treatment for neurosyphilis at the Public Health Institute³. Although many new patients have been treated with tryparsamide at this clinic since our report, only those seen five years ago are included here. A recheck could be made on only fifty-one, or about 60 per cent of the eighty-seven patients. Ten patients would not return in spite of numerous letters stating the nature of the free examination, thirteen had given fictitious names or addresses, two could not be located, two were duplicates, four were known to have died and five were being seen by private physicians from whom we were able to obtain a record. In the five groups, twenty-one of the thirty-four patients with asymptomatic neurosyphilis were reexamined, two of the four with meningovascular syphilis, eleven of the twenty with tabes dorsalis not having optic atrophy, seven of the twelve with dementia paralytica and ten of the fourteen with optic atrophy. The five groups had 4,297 injections of tryparsamide, totaling 11,075 Gm of the drug.

At the Northwestern University clinics seventy-one patients were registered as having been under treatment with tryparsamide. Of these only sixty-one, or 85 per cent could be traced. It is indeed disconcerting that all the patients reported by Lazar⁴ except the three

most interesting returned for examination. One of the three patients found by Lazar to have had acute blindness following an injection of tryparsamide was known to be dead, but no autopsy had been made. The patients were divided into four groups, with a record of 1,550 injections, totaling 3,151 Gm of tryparsamide.

The patients attending the Michael Reese clinic were divided into only three groups. Of the twenty-eight having records of tryparsamide therapy only twenty-six, or 93 per cent, had been observed up to the present. Injections to the number of 370, involving the use of 374 Gm of tryparsamide, were given to these patients.

The total number of injections given in all three clinics was 6,217, with the use of 14,600 Gm of tryparsamide.

The regular procedure in the administration of tryparsamide differed somewhat in each of the three clinics.

At the Michael Reese Hospital the patient was sent to the Eye Clinic for study of the visual acuity, the visual fields and the fundi before the series of injections was begun. Patients with optic atrophy were rejected for tryparsamide treatment. Weekly doses of 1 Gm were injected, and if there were no subjective complaints by the patient, who had not been informed of the possibility of optic complications, the patient was not returned to the Eye Clinic until a new series was to start. It is pertinent that visits of patients to the Eye Clinic were not numerous.

In the Eye Clinic of Northwestern University Medical School visual fields, visual acuity and fundi were studied before each injection up to and including the tenth. Subsequent examinations were done on visual complaint of the patient or on my request in order to compare ordinary fields with the flash fields⁵. No patient with defects in the fields or known optic atrophy was accepted by the Skin Department for treatment with tryparsamide. If ocular symptoms occurred injection of the drug was delayed until all symptoms disappeared and reactions were normal.

The Public Health Institute has a resident ophthalmologist, Dr Justin J. Korwin, who reported on the visual fields, visual acuity and fundi of all patients prior to their receiving tryparsamide. The patient was told of the possibility of ocular complications, and because of this suggestion many examinations of the eyes were requested. How vivid an impression the suggestion made was shown by the fact that frequently when the dose was increased from, for example, 2 to 3 Gm the patient, seeing this recorded, might have symptoms. At times a sterile hypodermic was given and 3 Gm recorded. In almost every instance the patient had ocular complaints. After the tenth injection no routine examinations were done except when ocular symptoms were noted. Consultation with the syphilologist, Dr Jarold Kemp, was accorded every patient with optic atrophy before the indicated use of tryparsamide was decided on. Treatment of all patients having symptoms referable to the eyes was discontinued until reactions were normal and symptoms had disappeared, when the course was resumed.

RESULTS

The patients at the Michael Reese Hospital were divided into three groups. (1) eleven patients with

asymptomatic neurosyphilis, (2) twelve patients with tabes dorsalis and (3) five patients with dementia paralytica

Of the patients with asymptomatic neurosyphilis, only one showed a change in visual acuity—an increase from 20/30 to 20/20. All fields remained normal.

In the patients with tabes dorsalis, visual acuity was changed in nine eyes. One patient showed a decrease from 20/20 to 20/30 in the vision of the left eye. The other eight eyes showed an increase in vision, namely, from 20/30 to 20/20, from 20/50 to 20/30, from 10/200 to 20/200, from 20/30 to 20/20, from 20/30 to 20/20, from 20/20 to 20/15, from 20/35 to 20/20. There was no change in visual fields in any of these patients.

Of the patients with dementia paralytica, only one showed a change in visual acuity. This was an increase in the vision of the right eye from 20/200 to 20/40 and in the vision of the left eye from 20/400 to 20/30. No changes in the visual fields were noted in any of these patients.

It is evident that the entire group from the Michael Reese Hospital, receiving doses varying from as little

In the group with meningovascular syphilis, changes in visual acuity were recorded for sixteen eyes. Five eyes showed a decrease in vision. One patient showed a decrease from 20/25 to 20/50 in each eye, but this was questioned because of the patient's mental status, another, a decrease from 20/30 to 20/15 in each eye, and the third, a decrease from 20/15 to 20/20 in one eye. Eleven eyes showed an increase in vision, namely, from 20/25 to 20/15, from 20/20 to 20/15, from 20/15 to 20/13 for each eye, from 20/25 to 20/16, from 20/25 to 20/20, from 20/30 to 20/20 for each eye, from 20/25 to 20/20 and from 20/50 to 20/20 for one eye and from 20/40 to 20/20 for the other. In only one patient was there a questionable change in visual field, but because of mental changes no ocular field could be taken. Subjective reactions were observed five times in four patients, but no permanent changes were noted in the optic nerve.

In the group with dementia paralytica, changes in visual acuity were recorded for thirteen eyes. Six eyes showed decrease in vision, namely, from 20/15 to 20/20, from 20/15 to 20/25, from 20/50 to 20/70, from 20/30 to 20/70, from 20/20 to perception of light

* Perception of light

as 3 Gm to as much as 30 Gm, with the injection of only 1 Gm at a time in the majority of cases, cannot be a criterion for patients getting larger doses and a greater number of injections. However, the evidence that no reactions were noted and no visual fields changed and that in only one case was there a slight lowering of visual acuity while in eleven eyes vision was enhanced certainly make it appear that tryparsamide caused little or no toxic effects.

The patients treated at Northwestern University were grouped as follows: (1) twenty-eight patients with asymptomatic neurosyphilis, (2) nineteen patients with meningovascular syphilis, (3) fifteen patients with dementia paralytica and (4) eighteen patients with tabes dorsalis.

In the group with asymptomatic neurosyphilis, a change in visual acuity was recorded for thirteen eyes. Four eyes showed a decrease in vision, namely, from 20/15 to 20/25, from 20/15 to 20/20, from 20/15 to 20/20 and from 20/20 to 20/30. Nine eyes increased in vision, viz, from 20/15 to 20/13, from fingers at 1 foot (30 cm) to 5/200, from 20/40 to 20/25, from 20/20 to 20/13, from 20/25 to 20/20, from 20/20 to 20/15, from 20/20 to 20/15, from 20/20 to 20/15 and from 20/20 to 20/15. In addition there was a change in visual field in one case, from homonymous hemianopia of the left eye to a normal field. One patient had two subjective reactions after injections of 2 Gm of the drug.

and from 20/13 to 20/30. Increase in vision was shown in seven eyes, viz, from 20/15 to 20/13, from 20/15 to 20/12, from 20/15 to 20/13, from 20/20 to 20/13, from 20/15 to 20/13 and from 20/25 to 20/20 for each eye. Changes in visual field were noted in three patients, homonymous hemianopia of the right eye without reaction developed in one, and one patient had the left field reduced from 20 degrees to zero after a 1 Gm dose. Three patients had the field of one eye reduced to 20 degrees after a 1 Gm dose. In addition two other patients had entirely subjective reactions.

Changes in visual acuity were recorded for six eyes of the patients with tabes dorsalis. Two eyes decreased in vision, namely from 20/20 to 20/25 and from 20/13 to 20/15. Four eyes increased in vision, viz, from 20/20 to 20/13, from 20/20 to 20/15, from 20/25 to 20/20 and from 20/30 to 20/25. No changes in visual field were seen in this group, and the only reactions were edema of the lid in one patient and nausea in another.

To summarize the data on the seventy-one patients from the Northwestern University Medical School Clinics in seventeen eyes vision was decreased while in thirty-one visual acuity was enhanced. Three patients with dementia paralytica lost field, one becoming blind while in one patient a hemianopic field returned to normal.

The patients at the Public Health Institute were grouped as follows: (1) twenty-one patients with

asymptomatic syphilis, (2) two patients with meningovascular syphilis, (3) eleven patients with tabes dorsalis without optic atrophy, (4) seven patients with dementia paralytica and (5) ten patients with optic atrophy

In the group with asymptomatic syphilis, six eyes showed changes in vision, the vision in both eyes being enhanced from 20/30 to 20/20 in three cases. No changes in visual field were noted in this group, and only three reactions were recorded, a slight, a moderate and a severe subjective reaction. The least amount of tryparsamide given to a single patient was 112 Gm and the greatest 511 Gm.

The patients with meningovascular syphilis showed no changes in visual acuity or visual field and no reactions. The least amount of the drug given was 65 Gm and the greatest 425 Gm.

In the group with tabes dorsalis without optic atrophy, three eyes showed visual changes, the vision of each improving from 20/30 to 20/20. No changes in visual field were noted in this group and only two reactions, one subjective and the other hysterical. The least amount of tryparsamide given was 11 Gm and the greatest 338 Gm.

In the group with dementia paralytica, only one eye showed a change in vision, and this was an enhancement from 20/30 to 20/20. No changes in visual field were found, and there were no reactions. The least amount of the drug given was 51 Gm and the greatest 443 Gm.

The accompanying table shows the data on the group with optic atrophy, and I should like to call particular attention to it because these were cases of known optic atrophy in which, in spite of the so-called contraindication, the use of tryparsamide was deemed advisable because of the patient's general condition. Eleven eyes showed changes in vision. The vision of two was decreased, from 20/40 to 20/50 and from 10/200 to perception of light, respectively. Nine eyes had an increase in visual acuity, viz, from 20/50 to 20/20, from 20/200 to 20/20, from 20/100 to 20/20, from 20/30 to 20/20, from 20/40 to 20/20 and from 20/30 to 20/20 for both eyes in two cases. Changes in visual field were noted in three cases—from 60 degrees to normal for both eyes in two cases and a decrease from 50 to 20 degrees for the right eye in one case. Subjective reactions were noted on two occasions in this group.

To summarize the data on the groups from the Public Health Institute, consisting of fifty-one patients observed for a ten year period, two eyes lost vision, one becoming blind for all practical purposes, while nineteen showed an improvement of visual acuity. Four eyes had their visual fields increased from 60 degrees to normal, while in one eye there was a diminution from a contracted field of 50 degrees to one of 20 degrees.

COMMENT

Of the entire group of 155 patients, 54 were observed from an ocular point of view for at least five years and a few for as long as ten years. In only two eyes, or 1 per cent, did blindness ensue, while four eyes lost visual field to a degree. It is not my purpose to argue whether these impairments were due to tryparsamide to the neurosyphilis or to both. However it must be admitted that the patients were poor risks for any kind of treatment. In view of the fact that visual

acuity and visual fields were decidedly improved in so many instances, it would seem fair to state that tryparsamide under proper control is less dangerous than at first considered, even if optic atrophy has already become apparent. Moore's⁶ statement that "tryparsamide is absolutely contraindicated in the treatment of the syphilitic optic atrophies," Stokes's⁷ contention that tryparsamide is contraindicated "when disease of the optic nerve is present (not the vascular mechanism)," and the statement of Bluemel and Greig⁸ that tryparsamide is "a form of therapeutic dynamite, notable chiefly for its dangers," do not agree with my experience. On the other hand, many reports, namely, those of Lillie,⁹ Cady and Alvis,¹⁰ Dancy,¹¹ Neff,¹² Roth,¹³ Casten,¹⁴ Lees,¹⁵ Hyder,¹⁶ Wile and Wieder,¹⁷ Lichtenstein,¹⁸ Cormia¹⁹ and others, and, more recently, the experience of Cordes²⁰ and of Fine and Barkan²¹ agree with my results, indicating that "the percentage of danger from tryparsamide is no greater than that from some other preparations providing the proper precautions are used,"²⁰ and that "the proved therapeutic value of tryparsamide, in a disease which is 'a medical emergency' justifies the slight risk."²¹

It is evident that a certain small number of patients with syphilis of the central nervous system have involvement of the optic tracts which may lead to blindness even without specific treatment. It is also acknowledged that an even smaller number of such patients when given tryparsamide may have subjective or objective signs and symptoms of injury to the optic tracts. Whether this minimal degree of danger is due to a direct toxic effect of the drug on the retina or optic nerves, to a particular sensitivity of the patient to the drug, to the toxic effects of the disease on the optic nerve, to arterial spasm caused by the drug or the disease or to the noxious influence of the treatment for syphilis during a period of low blood pressure, as hypothesized by Lauber,²² the low incidence of damage fully justifies the use of tryparsamide with proper observation.

CONCLUSIONS

From observation of 155 patients with various types of syphilis of the central nervous system, treated with tryparsamide and under rigid ocular control for a reasonable period of years, the following conclusions may be drawn

1 Subjective reactions are not infrequent but are often due to suggestion

2 Severe objective signs of damage to the optic nerve occur infrequently with reasonable ocular control

3 Of patients treated with tryparsamide, the percentage of those benefiting so far as the optic nerve is concerned is far greater than the percentage of those in whom damage may occur

4 Patients with optic atrophy due to syphilis should have the advantage of the use of tryparsamide when the drug is indicated

ABSTRACT OF DISCUSSION

DR. FREDERICK C. CORDES, San Francisco. The accounts in the literature have been so varied that there has been a great deal of discussion as to the safety of tryparsamide. This has resulted in a fear of blindness that has done a great deal to deprive many patients with neurosyphilis of one of the most useful of all drugs. There can be no doubt that the use of tryparsamide carries a certain danger comparable to that encountered in the use of any powerful drug, including arsenamine. That the optic pathways are vulnerable at times is also conceded. In just what manner this damage occurs is still unsettled. In considering this problem, two factors should be borne in mind. 1. Certain patients are sensitive to tryparsamide, as they may be to other drugs. 2. At times syphilitic optic atrophy has a tendency to progress rapidly without the use of any specific therapy. It is rather generally conceded that in cases in which there is no damage to the optic tract the risk is very slight, provided one is alert to the early warning of the subjective symptoms or objective signs. When symptoms appear, one must assume that the patient is sensitive to the drug, and in these cases it must be discontinued or used with a great deal of discretion. In the cases of optic atrophy shown in chart 12 there was a decrease in central vision in two patients, and in each instance this was limited to one eye. The visual field changes also are interesting. In only one case was there a decrease in the field of vision in one eye. From this it seems fair to assume that (1) the drug was not responsible for the decrease in vision and field, or both eyes would have been involved, (2) the process was too active or too far advanced to be benefited by the drug. This series of cases coincides with my experience that optic atrophy in itself is no contraindication to the use of tryparsamide provided the case is carefully controlled for evidence of sensitiveness to the drug. It is imperative that all these patients be watched carefully for the symptoms and signs associated with sensitiveness to the drug. I should like to emphasize the necessity of complete examination before the first treatment. There have been two patients who reported with the history of blindness following the use of tryparsamide. On investigation, it was found that there was no record of examinations of visual acuity, fields or fundus before the therapy was instituted. Obviously these cases are of no value in determining the effect of the drug. More large series of carefully controlled and observed cases should be reported so that it will be possible to determine definitely what the contraindications may be to the use of tryparsamide.

DR. WALTER I. LILLIE, Philadelphia. The number of cases presented is large, and the period of treatment is of sufficient duration not only to obtain a good clinical conception of the value of tryparsamide as a therapeutic agent but also to support my contention as well as the contentions of Cady and Alvis,

Dancy, Neff, Rotli, Casten, Lees, Hyder, Wile and Wieder, Lichtenstein, Cormia, Cordes, Fine and Barkan, and others that tryparsamide is not more dangerous from the visual standpoint than other preparations used in the treatment of syphilis of the central nervous system. Proper ocular supervision should be instituted for all cases treated, regardless of the therapeutic agent, as it is a well established fact that syphilis alone may and does cause progressive damage to the optic nerves, with resulting loss of peripheral or central vision, or both. No one has definitely proved that tryparsamide or any other arsenical is neurotropic. The type of field changes occurring before, during or after a proper therapeutic regimen has been instituted are similar to those occurring in untreated syphilis, and as yet no pathognomonic field defect due to tryparsamide has been demonstrated. I believe, as does Mayer, that suggestion may play an important part in the production of subjective symptoms, while the organic changes are best explained by a direct syphilitic process in the optic nerves, namely, a perineuritis. If tryparsamide is of value in arresting active syphilis of the central nervous system it should also be of value in arresting active inflammation of the retina, choroid or optic nerve, and the presence of the latter should be no contraindication to its use. I am sure that ophthalmologists are all agreed that an untreated active syphilitic process of either the central nervous system or the visual apparatus has a very unfavorable prognosis, so that any antisyphilitic therapeutic agent which will arrest or improve the condition should be used regardless of the pathologic condition existing when the therapeutic regimen is instituted. Reliable statistics prove conclusively that in inadequately or untreated syphilis of the central nervous system the occurrence of blindness due to optic atrophy is about 35 per cent. The comparison of this percentage to the reported 2 to 10 per cent of blindness occurring during treatment with tryparsamide suggests that tryparsamide is preventing the development of optic atrophy sufficiently marked to affect the central visual acuity in about 25 per cent of the cases. Dr. Mayer has presented in an orderly and comprehensive manner a sufficient number of cases, thoroughly examined ophthalmologically before, during and after treatment with tryparsamide, to justify the conclusion that this form of treatment, properly supervised by the syphilologist and ophthalmologist, is decreasing the incidence of optic atrophy in all types of syphilis of the central nervous system. My experience, with similar cases parallels that of Dr. Mayer, and I am in accord with his conclusions in every respect.

DR. LEO L. MAYER, Chicago. Dr. Cordes has added some important points which, because of the limited time at my disposal, I was unable to include in this portion of the paper. One of these was the fact that the majority of patients not benefited by tryparsamide were in a precarious state before the drug could be given and thus lost the proper chance for the evaluation of any type of therapy. Another point that Dr. Cordes mentioned which should be stressed is the complete visual examination before any type of antisyphilitic treatment. If the pretherapeutic status is not recorded, the progress and final results obtained have little basis for comparison. The plea of Dr. Cordes for more large series of such syphilitic patients certainly has my endorsement. Dr. Lillie has also emphasized the necessity of proper ocular supervision of neurosyphilitic patients, regardless of the therapeutic agent. I agree with Dr. Lillie. According to my experience no field defect characteristic of a tryparsamide effect has been obtained. It is also important to emphasize the fact that perimetry must be included as an important factor in the treatment of neurosyphilis. I want to add an additional case to this group which Dr. Gifford called to my attention before I left Chicago. A patient had come to the clinic at Northwestern University for tryparsamide treatment and had had fields, fundi, and visual acuity taken. He had then had six injections of tryparsamide without returning to the eye clinic, and when he did return, after this sixth injection, his fields were reduced to 5 degrees of the center in both eyes. The visual acuity was not reduced, as there was no central scotoma. I simply want to add that there was one case in which it seemed that there might have been an ocular effect from the administration of the tryparsamide itself.

IMMUNITY TO SMALLPOX

M W HUSBAND, MD

AND

DAVID T LOY, MD

MANHATTAN, KAN

In 1936 Bull and Rankin¹ reported the results of vaccination against smallpox in 5,000 college students at Lehigh University, Bethlehem, Pa. From their results they estimate that more than thirty-three out of each thousand American students entering college have never been vaccinated for smallpox and further that seventy-five out of each thousand college students are without adequate protection against smallpox.

In the same year a more extensive survey was reported by Collins². This survey includes studies of the rural, urban and metropolitan general white population of the United States and records data on the history and frequency of vaccination against smallpox in 9,000 families. Collins found that approximately 70 per cent of the adults had a positive history of

vaccination. These three students came from families in which the parents were devout Christian scientists.

The accompanying table gives in tabulated form the detailed histories and results of the vaccinated group. This group of college students included 739 males between the ages of 16 and 31 years inclusive. Of these 739 male students 628, or approximately 85 per cent, were in the age group 17 to 20 years inclusive. Two hundred and ninety-nine of the total group were females between the ages of 16 to 28 years inclusive. Of these 299 female students 270, or approximately 90 per cent, were in the age group 17 to 20 years inclusive. Approximately 80 per cent of the students in this group came from rural areas and small towns in the state of Kansas.

The following data are significant of a particular age group, predominantly 17 to 20 years inclusive, derived very largely from rural areas and the small towns of Kansas. To date no such study has been recorded in this state.

Of this group 192, or 18.4 per cent, gave a negative history of a previous vaccination against smallpox or

Total			1033	115	826	35	77	7	400	362	203	73	8

There were seven patients with negative vaccinations and eight who failed to return for examination leaving 739 males and 299 females or a total of 1,038 with complete record. This group gave histories of previous vaccinations therefore leaving 811 total for previous vaccination. Chickenpox is recorded only in those cases which gave a negative history of previous vaccination and smallpox. A total of ninety-two students stated that they had had chickenpox.

vaccination or had had smallpox at some time. Of this 70 per cent, 65 per cent had been vaccinated. This survey showed that there was a larger percentage of vaccinations in cities than in rural districts.

In September 1936, 1,053 students who were matriculating for the first time at Kansas State College were vaccinated against smallpox. Such vaccination at Kansas State College is not compulsory, but by following the method advocated by Diehl,³ that of vaccinating unless the student offers active resistance, there were only three students of the total group who refused

of smallpox. Eight hundred and eleven, or 78.1 per cent, gave a positive history of previous vaccination against smallpox and had a visible scar. Thirty-five, or 3.5 per cent, had not had a previous vaccination but gave a positive history of smallpox.

Each student was examined on the second, fourth and seventh days and later if indicated following the date of vaccination. The results were recorded according to the following classification: (a) Immune or immediate reaction—the development of a small area of redness with or without the presence of a papule, the height of the reaction being reached within twenty-four to forty-eight hours following vaccination. (b) Primary take—the formation of a papule, vesicle and pustule, the height of the reaction being reached within six to ten days following vaccination. (c) Secondary take

same as primary take except that it occurred in an individual with a visible vaccination scar or with pockmarks (d) Accelerated reaction same as primary take except that the reaction was less pronounced, developed more rapidly and disappeared in a much shorter period of time

The following results were obtained from the vaccinations. Four hundred, or 38.5 per cent, had immune or immediate reactions, 362, or 34.9 per cent, had accelerated reactions, 203, or 19.6 per cent, had primary takes, and seventy-three, or 7 per cent, had secondary takes. Only four had systemic reactions of sufficient severity to warrant special medical care. These students made a rapid recovery. The multiple puncture method was employed on the skin site over the insertion of the deltoid muscle in all instances. No dressings or protective shields were used and no secondary infections were encountered. No instance of generalized vaccinia occurred in the group vaccinated.

It may be noted that there are more primary takes recorded than there are students who gave an entirely negative history. We feel that this can be accounted for in the error in the histories of those stating a positive history of smallpox. None of these students had pockmarks and they probably had had chickenpox instead of smallpox.

Apparently the percentage of students with previous vaccination is considerably higher in Pennsylvania than in Kansas. This tends to bear out Collins's observation that vaccination is more frequent in cities than in rural districts. However, the percentage of students with previous vaccination in our study is higher than the percentage found for the general population.

SUMMARY

1 Of the group vaccinated, 26.6 per cent had no protection against smallpox.

2 Thirty-four and nine-tenths per cent (accelerated reactions) had only partial or impaired immunity to smallpox. We feel that it is reasonable to assume that this group is susceptible to smallpox in a milder form and capable of transmitting the disease to non-immune contacts in a more severe form. Therefore, this group represents a potential public health problem.

3 Sixty-one and five-tenths per cent (primary takes, secondary takes and accelerated reactions) were in some degree susceptible to smallpox.

4 Revaccination restores or reinforces protection against the disease and it is an acceptable procedure from the point of view of the students.

5 The only practical method for reaching the students who are without adequate protection is by vaccination of each entering student. Moreover, these students who go out to become leaders in their communities should be educated as to what constitutes adequate protection against smallpox.

Comprehensive Attack on Traffic Noise—Three reports on road transport noise have been issued by a Departmental Committee set up by the Minister of Transport, and the position is that for the first time in Great Britain a comprehensive attack has been made on the problem of road traffic noise. To this end loudness measurements, many thousands in number, have been conducted under widely different working conditions on the over-all noise of some 800 motor vehicles, both new and old, representing all the main types on the roads today.—*Kave G. W. C. Noise and the Nation, Nature* Sept. 18, 1937, p. 490.

Clinical Notes, Suggestions and New Instruments

EFFECTIVE USE OF EPINEPHRINE INHALATIONS IN ANGIONEUROTIC EDEMA

EDMUND W. KLINEFELTER, M.D., YORK, PA.

The pathogenesis of angioneurotic edema is unknown. Ten years ago the chief emphasis was placed on the vasomotor and neurotic background. Since that time, however, the vasomotor and neurotic background has been receiving progressively less consideration, and increasing emphasis has been placed on allergy. Certainly, from the standpoint of successful treatment when an offending substance, food or protein, is shown to be the cause of an angioneurotic edema it should be removed, or there should be attempts made to desensitize the patient. But from the impression gained in reviewing the literature, and from my own experience, attempts to eliminate the offending substance and to desensitize have been largely unsuccessful. Consequently it would seem that this emphasis on the allergic background of angioneurotic edema is of small use from the practical therapeutic point of view. Perhaps the greater emphasis should rest on the older view that angioneurotic edema is a vasomotor neurosis.

If the vasomotor system plays a conspicuous part in angioneurotic edema, one might expect that a drug capable of influencing this system might influence the disease. Epinephrine exerts a marked influence on the vasomotor system and hence from the theoretical standpoint one might expect a beneficial influence on angioneurotic edema. But the practical application of epinephrine therapy in the past has fallen short of the theoretical expectations. This failure has been due to the fact that the method and manner of use of epinephrine have not been understood.

In this paper I call attention to treatment directed toward the vasomotor component in angioneurotic edema by the use of inhalations of epinephrine 1:100 solution as recommended by Graesser and Rowe¹ for bronchial asthma. In the first place, it should be emphasized that the effective time to employ inhalations is before or at the very outset of an attack. A warning sign or symptom will often tell the patient of an approaching attack. Then from two to three inhalations of the epinephrine should be taken at once and repeated every five to fifteen minutes until the warnings disappear and there is no evidence of swelling. For their curative effect and after the threat of the acute attack has faded three inhalations should be taken every two hours during the day and on alternate days over a period of from three to five weeks. If during this period an acute attack threatens the more frequent administration of the inhalations should be resorted to.

By this method excellent clinical results were obtained. After a few inhalations acute attacks were quickly aborted and continued use appeared to exert a curative influence. Even the case of long standing responded well to this treatment. No significant side effects were noted. The following case illustrates the excellent results obtainable from inhalations of epinephrine.

REPORT OF CASE

A single woman, aged 24, a stenographer, well developed but neurotic, had suffered typical attacks of angioneurotic edema of the eyelids for the past ten years. Lately the attacks had been increasing in number and severity. Fits of sneezing and a feeling of tightness in the eyelids always preceded an outbreak. Within half an hour the eyes would become completely buried beneath thick, sausage-like translucent swellings the size of a hen's egg. Vision was impossible. The swellings were pale and slightly itchy. They were always well defined and did not pit on pressure. Within a day or two they disappeared without leaving a trace.

The physical examination revealed nothing otherwise of interest excepting an unstable vasomotor system. Laboratory studies disclosed nothing abnormal. The blood Wassermann

¹ Graesser, J. B. and Rowe, A. H. Inhalation of Epinephrine for Relief of Asthmatic Symptoms. *J. Allergy* 6:415 (July) 1935.

reaction was negative. The urine contained no albumin, sugar or hematoporphyrin. Skin tests and elimination diets showed sensitiveness to a variety of proteins and foods.

The patient without improvement had been subjected to practically all the measures usually recommended for the disease, including a milk and cereal diet, specific desensitization, elimination diets, calcium gluconate, quinine and antipyrine, atropine, bromides and phenobarbital, acid therapy, alkali therapy, peptone desensitization, autohemotherapy, typhoid vaccine, biliary drainage, high voltage roentgen therapy to the cervical roots, and short wave diathermy. During the attacks local applications of cold compresses to the swellings, injections hypodermically of epinephrine, and capsules orally of ephedrine were thought to be of slight benefit.

On examination May 3, 1936, a spell of sneezing started and the patient experienced a feeling of tightness in the eyelids. They started to swell and immediately 1:100 epinephrine solution was inhaled. After the first three inhalations the feeling of tightness disappeared and there was no further increase in the swelling. Three inhalations were taken every fifteen minutes for three hours, and then the interval between inhalations was lengthened to two hours for the remainder of the day. Subsequently three inhalations were taken every two hours on alternate days over a period of five weeks. Since this period of treatment no further inhalations have been necessary. The patient now has suffered no angioneurotic swellings for over a year, whereas prior to this treatment for more than ten years not a single month passed without one or more attacks.

COMMENT

A survey of the literature on the treatment of angioneurotic edema with epinephrine revealed only a small number of reports. Codd² in 1917 reported the cure of a case of angioneurotic edema by the use of epinephrine hypodermically and tablets orally. MacGowan, Longcope and others, cited by Menninger,³ feel that epinephrine may be of occasional benefit. Recently Hughes⁴ reported a case of angioneurotic edema of the throat in which he attributed improvement to epinephrine used hypodermically and as a spray, together with capsules of ephedrine orally. Nevertheless, from the literature and from my own experience the impression was gained that epinephrine as formerly used was of doubtful value in this disease. To be sure, little or no benefit can be expected from the use of epinephrine in the acute case after the swellings have fully developed. The important factor, therefore, in the management of angioneurotic edema, which has received no emphasis in the literature, is the early administration of epinephrine before or at the very earliest development of the swellings.

Although it is stated that these swellings not infrequently develop without warning, most patients will present a sign or symptom before or early in the attack which will permit the use of epinephrine in time to be effective. Numerous preceding or concomitant signs of angioneurotic swellings have been mentioned in medical writings. Hughlett⁵ states that attacks may be preceded by redness, heat, itching or urticaria and that they are almost always accompanied by a feeling of tension in the skin of the affected part. Abdominal pain of a colicky nature is mentioned frequently as preceding or accompanying attacks of angioneurotic edema. Frieboes⁶ calls attention to the fact that for several hours preceding an outbreak the patient may be warned by an internal feeling of nervousness and restlessness. And Oliaro⁷ mentions numerous cerebral symptoms accompanying or preceding an attack of angioneurotic edema such as lassitude, tremors, drowsiness, a numb feeling in the head, dizziness, paresthesias in the extremities and transitory oculomotor paralysis.

The institution of epinephrine inhalation therapy marked a great advance in the treatment of bronchial asthma. The

employment of this treatment shows promise of a comparatively greater advance in the management of the more serious angioneurotic edema. However, it should be mentioned here that a search of the literature disclosed no report in which epinephrine inhalations were employed in the treatment of this disease. Furthermore, although I am aware that angioneurotic edema often appears and disappears without apparent reason, the continued use of the inhalations seems to exert a definite curative influence.

SUMMARY

1 Oral inhalations of epinephrine 1:100 solution have been found effective in preventing the development of angioneurotic swellings.

2 The necessity has been stressed of the early use of epinephrine inhalations before or shortly after the swellings have started.

3 Epinephrine in the fully developed acute case has been found of little benefit in reducing the swellings.

4 Continued use of inhalations of epinephrine in angioneurotic edema appears to exert a curative influence.

REACTION TO SODIUM MORRHUATE INJECTIONS FOR VARICOSE VEINS AND HYDROCELE

J. TECUMSEH N. McCASTOR, M.D.

AND
MARY COUSINS McCASTOR, M.D.
NEW YORK

Having read of severe general reactions following the injection of sodium morrhuate into a varicose vein in an article by Dr. Maurice L. Dale in *THE JOURNAL* for Feb. 27, 1937, and in an article by Dr. Kenneth M. Lewis in the issue of Oct. 17, 1936, we report our case to emphasize the possible dangers of this form of therapy.

W. J., aged 30, was treated on March 12, 1937, with the injection of 5 cc. of 5 per cent sodium morrhuate (Kirk) into the right leg below the knee. At that time he made no complaint and no reaction was discernible. On March 18 the injection was repeated. The patient's face quickly turned pale and the lips blue. He was advised to recline on the table for about five minutes, after which he said he felt "all right" and outwardly appeared so. We asked him to remain in the waiting room while we turned our attention to another case. After ten minutes he said to the assistant, "I feel very good now, I think I shall go." Arising, he took two steps to the corner of the room to reach for his hat and coat and then suddenly collapsed, his head striking the floor with extreme violence. The pulse was imperceptible, respiration had ceased, the face was cyanotic, the pupils were dilated and the balls of the eyes were rolled upward toward the head and were glassy. To all outward appearance he was dead. He had lost control of the sphincter of the bladder. His clothing was loosened, artificial respiration was instituted and 5 minims (0.3 cc.) of epinephrine was injected into the jugular vein. The injection was repeated in two minutes, and an ampule of coramin was injected subcutaneously. At the end of four minutes the patient gasped and respirations were restored. The pulse was thready and irregular. The sodium morrhuate had been given at twenty minutes to six in the evening. At 6:30 the pulse rate was 60 and the face had changed from blue to a pasty white. The lips were pallid and the eyes still glassy, but the reflexes had returned. At 7 p. m. the pulse rate was 82 and at 8 p. m. 84. The patient was unable to retain whisky, so an ounce of sherry wine (30 cc.) was given. He had previously taken a few sips of coffee. It was impossible to move him from the table for four and one half hours. The mere act of sitting up with aid to receive nourishment, caused fainting. He complained of extremely violent frontal headaches.

The case resembled that of Dr. Lewis's in that bradycardia was present, there was no rash of any kind and there were no bronchial or intestinal spasms. The patient did have a spasm of the muscles of both legs, he said, as high as the saphenous opening, and he described it as a shooting pain in both legs. Because of his condition, he remained overnight and in the morning he was able to return home. His history shows that in 1919 he had urticaria of such severity that it was

necessary for him to remain in bed for three weeks. At that time, he said, he received injections because of sensitivity to lamb and to cheese.

In the last year we have given over 2,500 injections for varicose veins, and this is the first such reaction to occur.

We wish to report also a reaction to the same substance which occurred at the giving of the second injection for hydrocele.

The first injection of 1 cc of Searle's sodium morrhuate into the hydrocele sac caused no pain or untoward symptoms of any kind. A week later the patient returned for his second injection, at which time 25 cc of sodium morrhuate was injected into the sac. Within two minutes the patient collapsed and complained of severe intestinal cramps and pain from the kidney region to the groin. Five-tenths cubic centimeter of epinephrine was administered, followed by one-third grain (0.2 Gm) of pantopon (a preparation containing the hydrochlorides of the alkaloids of opium, principally morphine). Three days later the scrotum was enlarged to three times its original size and caused considerable pain. A week later, after application of an ice bag, with elevation of the testicles and rest in bed, the patient was ambulant. He returned to our office, the scrotal sac was punctured and about 6 cc of straw-colored fluid was withdrawn. Three weeks later the scrotum was normal in size and no hydrocele was in evidence. There was no history of allergy.

UNUSUAL RELATION BETWEEN MENSTRUAL FUNCTION AND ASCITES IN A CASE OF JUVENILE CIRRHOSIS OF THE LIVER

SHATTUCK W. HARTWELL, M.D., PH.D., MUSKOGON, MICH.
AND
WALTER R. JOHNSON, M.D., ASHEVILLE, N. C.

The following case report is worthy of record for several reasons: first, because ascites was the outstanding symptom at all times; second, because a Talma-Drummond-Morrison operation plus omentopexy was performed in an attempt to reduce the degree of ascites; and as far as we can learn this is the first case of juvenile cirrhosis in which such a procedure was utilized,¹ and third, because there was apparently a remarkable relationship between the degree of ascites and the menstrual function. Observations have been carried out over a period of six years, and while no conclusions have been reached as to the mechanism responsible for the reduction of the ascites coincidently with the establishment of menstrual function, the observations seem in themselves to be sufficiently interesting to warrant inclusion in the literature.

Juvenile portal cirrhosis (Laënnec's atrophic nodular cirrhosis) is a condition rarely encountered. Sutton² in 1930 was able to find in the American literature but twelve proved cases of non-alcoholic atrophic cirrhosis in children. He added the thirteenth.

The patient, a girl of 18, had lived in Czechoslovakia until her eighth year. At the age of 14 she had pneumonia. Puberty had begun when she was 14, but her breasts had remained flat and infantile in appearance and catamenia had never been established. An older sister had not menstruated until her sixteenth year. Both parents, one brother and three sisters were normal and healthy in every respect, and there was no history of hepatic disease in any of the other relatives. In the patient's past history there was no record of alcoholism, unusual diet, exposure to chemicals or infection.

In the fall of 1929, at the age of 16 she began to notice slight enlargement of the lower part of the abdomen. This enlargement increased gradually, but no other symptoms were noted until the fall of 1930, at which time the distention of her abdomen had increased sufficiently to cause dyspnea on exertion. At this time she first consulted a physician. In April 1931, after a brief episode of mild jaundice without pain, she went to the University Hospital at Ann Arbor, Mich. Her outstanding complaints on admission were (1) marked ascites, (2) dyspnea on exertion and (3) amenorrhea and atrophic

breasts. Routine physical examination showed nothing abnormal except distention of the left jugular vein, a greatly distended abdomen with a distinct fluid wave, and a barely palpable liver. Temperature, pulse and respirations were normal throughout fifty-one days of observation. Laboratory tests gave negative results except that they revealed basal metabolic rates of minus eight and minus eighteen. X-ray studies of the sella turcica and the gastro-intestinal tract yielded nothing important. X-ray studies of the chest resulted in a roentgenologic diagnosis of congenital heart disease. On two occasions 4,000 cc of ascitic fluid was removed. Inoculations of guinea pigs with the ascitic fluid did not reveal tuberculosis. The final clinical diagnoses were (1) Pick's disease and (2) portal cirrhosis.

In November 1931 the patient registered at the Mayo Clinic. Paracentesis had been performed once in the meantime to reduce discomfort and dyspnea. Catamenia had not appeared and her only other complaints were dyspnea on exertion and marked enlargement of the abdomen. Except for extreme ascites, physical examination gave essentially negative results, as did routine tests of the blood and urine and serologic tests. No dependent edema or superficial collateral circulation was noted. Her weight at this time was 128 pounds (58 Kg). A test of the liver function with bromsulfalein showed grade 2 dye retention. The serum bilirubin content was 17 mg, and there was a direct van den Bergh reaction. Roentgenograms of the chest revealed a peculiar globular shadow in the mediastinum, which was at first interpreted as being the outline of a congenitally diseased heart. Further study, including fluoroscopic examination, indicated that this shadow was cast by an ovoid mass in the posterior mediastinum, definitely behind the heart. X-ray treatment produced no change in the size of this mass.

By means of ammonium nitrate given orally and salyrgan given intravenously, satisfactory diuresis was obtained. Several pounds of weight were lost, and the ascitic distention was materially reduced. The patient felt definitely more comfortable, and she was allowed to return to her home in Michigan. The clinical diagnoses made were (1) juvenile cirrhosis of the liver, (2) amenorrhea and (3) mediastinal tumor of unknown nature.

She was first seen by one of us (S. W. H.) Dec. 15, 1931, because of an increase in the degree of ascites. She was apparently well otherwise except for dyspnea on mild exertion. Three days later 9,000 cc of straw-colored ascitic fluid was removed from her abdomen. After this procedure a firm liver could be palpated extending across the entire right upper part of the abdomen and the upper one half of the left upper quadrant. The ascitic fluid reaccumulated rapidly, and on Jan. 7, 1932, with the patient under ether anesthesia, 7,000 cc of fluid was withdrawn by paracentesis, after which an exploratory incision was made in the upper part of the abdomen. Careful inspection of the abdominal contents revealed the organs, including the spleen and the peritoneum, to be normal grossly, except for the liver, which was moderately enlarged and which was a peculiar pale pink. Its surfaces were studded with tiny vesicles which could not be ruptured by the finger or by wiping vigorously with dry gauze. A large biopsy specimen was taken from the liver, and a Talma-Drummond-Morrison operation was performed together with an omentopexy.

Portions of the liver were sent to two responsible pathologic laboratories for study. One laboratory reported "biliary cirrhosis (with parenchymatous degeneration)", the other, "hepatitis (with portal cirrhosis)". The microscopic examinations failed to demonstrate the vesicles which had been so prominent on inspection of the surface of the liver.

The wound healed by primary intention and the patient made an uneventful recovery. She was dismissed from the hospital twenty days after operation. Three weeks later the ascitic fluid had reaccumulated to such an extent that she returned for further treatment. Six grains (0.4 Gm) of ammonium nitrate was given orally each day, and injections of merbaphen were begun, after which there was a marked increase in the urinary output and a concomitant decrease in the size and tenseness of the abdomen. During March and April of 1932 the abdomen measured approximately 92.5 cm in circumference and the patient's weight averaged about 119 pounds (54 Kg). She felt well and was able to help her mother with the housework.

On May 28, 1932, after vigorous dancing at a wedding the previous day, her first menstrual period began after which she felt greatly improved and stated that her abdomen was definitely smaller. Within a month, however, it again measured 92 cm. in circumference.

1 Nordland and Larson's omentopexy was done in 1932.
2 Sutton, T. Leonard. Cirrhosis of the Liver in Childhood. Report of a Case of Atrophic Cirrhosis in a Boy Aged Ten Years. *Am. J. Dis. Child.* 39: 141-142 (Jan.) 1930.

On Nov. 8, 1932, the patient entered the University Hospital at Ann Arbor for a second period of observation. Study of the ascitic fluid revealed a specific gravity of 1.019, alkaline reaction, grade 4 albumin and a negative reaction to Gmelin's test. There were 1,080 red cells and 230 white cells per cubic centimeter of fluid. Ninety per cent of the white cells were small lymphocytes. The serum bilirubin content was 2.5 mg., and there was a direct reaction. A dextrose tolerance test revealed a blood sugar content of 86 mg. during fasting, 103 mg. at the first hour, 90 mg. at the second hour and 100 mg. at the third hour. Concomitant specimens of urine did not contain sugar. A tick-tack rhythm of the heart and a paradoxical type of pulse were noted.

With the patient on a neutral diet with forced fluids plus ammonium nitrate orally and salyrgan intravenously, the ascites was reduced almost completely, and on April 19, 1933, she was dismissed from the hospital with a diagnosis of Pick's disease. Her weight on dismissal was 111 pounds (50 Kg.).

The patient continued the neutral diet and ammonium nitrate medication at home but the ascites soon recurred, producing for the first time marked edema of the lower extremities. Paracentesis was performed at the patient's home on May 9, and 10 pounds (4.5 Kg.) of ascitic fluid was withdrawn. Six weeks later her abdomen was again greatly distended, but she stated that she was able to control the distention to some extent by means of frequent doses of magnesium sulfate.

Because of the apparent improvement after her one and only menstrual period, an attempt was made to establish a normal menstrual cycle in the hope that there might be some connection between this function and the ascites. To this end progynon tablets were given orally, and a normal menstrual flow occurred, lasting from July 5 to July 9. For several days after this period her abdomen was distinctly less tense and she felt more comfortable. On July 20, however, the circumference of her abdomen was 98.5 cm., her weight was 135 pounds (61 Kg.) and a distinct para-umbilical hernia was noted. Twelve and one half pounds (5.7 Kg.) of ascitic fluid was removed at the patient's home. Palpation of the liver showed that it was definitely softer and smaller than on any previous examination. The administration of progynon tablets was continued and another normal menstrual period occurred on August 21. Again a definite decrease in the size of the abdomen and in the degree of discomfort was noted. A month later paracentesis again became necessary, and 13 pounds (6 Kg.) of fluid was removed. On October 1 another normal menstrual period occurred, and during the succeeding six months her weight gradually decreased from 132 to 121 pounds (from 60 to 55 Kg.), with a concomitant decrease in the circumference of her abdomen from 95 to 79 cm.

From May 12, 1934, to March 1, 1937, twenty-six normal menstrual periods occurred. At first the intervals between periods were two or three months long, but since June 1935 catamenia has occurred at intervals of from thirty-one to thirty-six days. For the first year of menstruation the patient's abdomen increased in size and tension during each menstrual period and during the preceding week. For several days after each period, however, it was so reduced in size that her clothing was noticeably loose. Since her periods have occurred regularly each month her abdomen has become progressively smaller and she feels better than she has ever felt before. She did housework for one year and for the last nine months has worked steadily in a factory. She has grown in height and there has been definite increase in the size of her breasts. Her weight in March 1937 was 140 pounds (63.5 Kg.), and the circumference of her abdomen was 92.5 cm. Formerly, when she was supine the ascites was sufficient to give her the appearance of a pregnant woman at full term. At present her abdomen is almost scaphoid when she is supine, and there is no ascites. In April 1936 the margin of the liver was palpable 7 cm. below the right costal margin. In March 1937 the liver was palpable for 5 cm. The spleen has never been palpable. Since the menstrual function was established in September 1933 there has been no need for paracentesis or medication designed to promote diuresis.

COMMENT

There is some difference of opinion both clinically and pathologically as to the nature of the disease process that is present in this case. A diagnosis of Pick's disease was made

by one group of investigators. Another group felt that the x-ray appearance of pericardial effusion was produced by a posterior mediastinal mass wholly separate from the heart. However, at one time or another both groups have made a diagnosis of portal cirrhosis. One pathologist, after a study of the liver tissue removed at operation made a diagnosis of "biliary cirrhosis with parenchymatous degeneration", the other concluded that the tissue represented "hepatitis with portal cirrhosis". These differences of opinion are not rare in the field of hepatic pathology, and as many students feel that the various pathologic pictures represent nothing more than different stages of the same degenerative-reparative process, we need not be too much concerned with the failure of the two pathologists to agree exactly. From a clinical standpoint the outstanding feature in this case has been ascites of hepatic origin. Whether the ascitic fluid developed as a transudate from the portal circulation secondary to portal obstruction due to portal cirrhosis, or as an exudate from the surface of the liver, as might be the case in Pick's disease, the problem was the control of the ascites. The use of the Talma-Drummond-Morrison operation offered the only permanent solution to the problem in either case, although its use has previously been recommended only in case of portal cirrhosis. Jaundice has constantly been lurking in the background, as the brief period of icterus six years ago and the more recent direct van den Bergh reactions of the blood serum indicate.

The other point of interest has been the sexual immaturity as evidenced by amenorrhea and undeveloped breasts. Such immaturity has been mentioned by several other writers in connection with juvenile cirrhosis. Barker³ noted the association of hypoplastic breasts and infantile uterus in a girl of 17 who had cirrhosis of the liver and ascites. Tramontano⁴ reported a case of splenomegaly atrophic cirrhosis in a 23 year old man who presented definite sexual infantilism. Reuben and Peskin⁵ noted "distinct evidence of infantilism" in an 8 year old girl with syphilitic cirrhosis.

A Talma-Drummond-Morrison operation plus omentopexy was performed on our patient in an effort to improve the collateral circulation and render paracentesis unnecessary. In 1932 a similar procedure was carried out by Nordland and Larson⁶ on a 6 year old child with Laënnec's cirrhosis. Deep jaundice was the outstanding complaint in their case, ascites being found only after the abdomen was opened. Successful palliation for a period of two years followed the operation. As far as we can learn, these two cases are the only ones reported in the American literature in which such an operation has been performed for juvenile portal (Laënnec's or atrophic) cirrhosis.

It may be argued that the improvement noted in our case in the last five years has been due primarily to the operation. Against this conclusion is the fact that sustained improvement did not occur for one year and nine months after it. Only after the menstrual function was well established did the need for frequent paracentesis disappear. While it is recognized that repeated paracentesis may eventually control the ascites in some adult cases of portal cirrhosis (and this possibility must be considered here), in this case our juvenile patient demonstrates very positively an intimate relationship between menstruation and the degree of ascites. As far as her subjective sensations were concerned, there was no doubt that she was far more comfortable immediately after the menstrual flow had ceased. Clinical observations tended to confirm her own observations, since the circumference of the abdomen decreased definitely after catamenia. The fact that paracentesis and attempts at diuresis have been unnecessary in the three years since menstruation began is perhaps the strongest proof that in this case a definite relationship exists between the menstrual function and the degree of ascites. Studies on premenstrual retention of water may shed some light on this interesting problem.

EQUIPMENT FOR AIR CONDITIONING

EMERY R. HAYHURST, MD

AUBREY I. BROWN, ME

Professor of Heating and Ventilating, Ohio State University
COLUMBUS, OHIO

AND

RICHARD KAHN, BME

DAYTON, OHIO

In the first and second reports of this committee, the purposes and objectives of air conditioning have been set forth by Yaglou,¹ one of the members of this committee. The control of conditions affecting comfort, health and efficiency in an artificial space environment involves a number of physical, chemical, biologic, and even psychic factors for which tentative standards have been suggested by various more or less authoritative groups.²

"Air conditioning" is the present term adopted for covering these factors but, as commonly used, this term does not embrace other environmental conditions, such as insulation, radiation, illumination and noise, which may be important collateral factors.

The present report deals solely with the equipment designed for procuring suitable conditioning of the air. A subsequent committee report will consider the instruments and procedures suitable for examining air conditions found or produced.

The practice of air conditioning in the more modern sense began about thirty years ago in industries in which the conditions of the air, mainly the temperature, humidity and dust content, were found to affect the quality of the product or the rate of production. However, the centrifugal fan for impelling or extracting air to and from large buildings is said by Bedford³ to have been invented by Desagulier more than 200 years ago, and artificial humidification has been used, for example, in cotton textile works for a long period.

In recent years it has been found that "manufactured weather"⁴ may be profitably applied to theaters and other places of public assembly, where the investment has proved justified by increased patronage resulting from greater comfort. Increase in revenue has been the prime motive for applying air conditioning to stores, hotels, cafeterias, railway passenger cars and office buildings. Comfort and health have been the chief motives in schools, churches, lodge halls and the like. Added to these reasons, safety (in the use of anesthetics) and other special clinical considerations have appealed to the hospital. More recently, interest has been manifested in the air conditioning of private offices and residences, where the results are valued not in terms of financial profit but in terms of improved comfort or health.

This is the third report of the committee established by the American Medical Association to study air conditioning. The first report appeared in *THE JOURNAL* May 15, 1937, p. 1708 and the second report September 18, p. 945. The committee includes Carey P. McCord, Detroit, chairman; Emery R. Hayhurst, Columbus, Ohio; William F. Petersen, Chicago; Horatio B. Williams, New York; and Constantine P. Yaglou, Boston.

Air conditioning, in general, involves control of the following factors: temperature, humidity, air motion, air distribution, dust, bacteria, odors and toxic gases. Of these, the first three—temperature, humidity and air motion—are usually the most important, while dust, bacteria and toxic gases present special problems (chiefly industrial), and air distribution and control of odor pertain to all air conditioning.

BASIC EQUIPMENT

Any discussion of equipment for the procurement of air conditioning must be built around continual references to certain widely used procedures and appliances. Figure 1 diagrammatically presents the conditioning equipment and procedures necessary to control the aforementioned factors during all seasons, showing the primary and essential steps of filtering, preheating, humidifying, heating, or cooling and dehumidifying, which precede the circulation and distribution of conditioned air as varied conditions might require.

Entirely distinct equipment is shown in the diagram for winter and summer requirements. In actual practice, much of the same equipment may be used in any season. The filter that cleans the air in winter performs the same operation in summer. The spray that humidifies in winter may be used through modification to dehumidify in summer. All these items required in the attainment of satisfactory air conditioning are now discussed.

FILTERS

The impurities removed by filters include carbon (soot) from the incomplete combustion of fuels in furnaces and automobile engines, particles of earth, sand, ash, automobile tires, stone, wood, rust and paper, threads of cotton, wool and silk, bits of animal and vegetable matter, pollen and some bacteria.

The commonest types of apparatus for cleaning air are dry filters. In these the air is filtered through screens made of felt, cotton fabric, cellulose or glass wool. The air is passed through so many devious channels that most of the dust is entrained on the way. Because of the close texture of the filtering mediums the velocity of the air passing through the filter must be low. This necessitates a relatively large surface, and in order to increase the effective filtering area without increasing the dimensions of the filter the filter mediums are usually arranged to form interstices (pockets).

Dry filters in which felt or similar materials are employed usually depend on vacuum cleaning for reconditioning, but many inexpensive dry filters are discarded when they become clogged and are replaced.

The use of a viscous fluid, such as oil, for the retention or collection of dust is a familiar practice. The housewife uses oiled cloths for "dusting" about the house. In cleaners employing the viscous film principle, air is drawn through a device containing a series of deflecting surfaces, usually of metal, these surfaces being coated with a viscous oil. As the air impinges against these surfaces it is deflected and passed, but the heavier particles of dust or foreign matter adhere to the viscous film.

Viscous filters are of the automatic or nonautomatic type. The nonautomatic unit or cell type consists of two panels of metal screen enclosed in a frame of convenient size for handling. Filling the space between the front and back screens are packed mats of split or crimped wire or glass wool, which is impregnated with the viscous oil.

When these filters become clogged they must be cleaned out and recoiled. A more recent development is the use of units of light and inexpensive construction which are discarded and replaced when dirty.

Automatic filters of high air capacity are designed to be self cleaning. They consist of an endless vertical chain or belt of filter material arranged over a top and bottom sprocket, and moving continuously. Clean surfaces are constantly presented to the air stream, and dirtied sections pass through a tank of viscous oil at the bottom to wash off the dirty oil and recoat the belt.

The air washer is similar in effect to the cleansing action of a rainstorm on the atmosphere. Spray nozzles are placed in the path of the air, and water is discharged from them in the form of a fine mist. The incoming air is thus brought into intimate contact with the water. At the outlet to the washer are a series of zigzag plates which cause the air to change direction violently, so that the dirt is thrown out from the air by its inertia. Recent developments offer the promise of electrical precipitation as a means for the removal of ordinary dusts and bacteria.

WINTER CONDITIONING

Heating—In air conditioned spaces, direct radiation from steam or hot water radiators may be provided to make up the loss of heat from the building. In these cases the forced air circulation system supplies outdoor air in quantities sufficient for ventilating purposes only. This outdoor air must be heated to room temperature before its introduction into the occupied space.

the two previous reports of this committee¹ the necessity for humidifying or moistening the air for comfort conditioning (used only during the winter) has not been substantiated. A relative humidity of from 30 to 60 per cent is regarded as a desirable figure for the most healthful conditions. In cold weather, humidities above 30 per cent will cause condensation on single

Fig 2—Spray type air conditioning apparatus

windows, however, and for this reason humidities above this figure should not be provided unless provision is made against condensation by the installation of double glass windows.

In order to preclude the possibility of freezing the water used for humidifying, it may become necessary to preheat the outside air entering the conditioning system.

Humidifiers may be classified as direct, which introduce moisture directly into the room, or indirect, which introduce moistened air. Surface humidifiers are the simplest types of moistening devices. These consist of pan type containers providing a large water surface and equipped with some means of heating the water in order to force evaporation. This heat may be applied by electricity, steam or hot water. When heat is not applied directly to the water, the heated air may be directed across the surface of the pan. This area may be increased by the use of fabric strips dipped into a supply of water and wetted by the capillary action through the material. When a large volume of air is to be moistened it is difficult to provide sufficient surface for adequate capacity, and other methods of humidification must be adopted.

In large central air conditioning systems a spray humidifier may be used to humidify the air. The air may be preheated before entering the humidifier so that its ability to evaporate moisture is increased, or the spray water with which the air is brought into intimate contact may be heated to accomplish the same purpose. When there is no central humidifier in the system, room humidifiers may be used. In these the air is passed through a direct spray, where a part of the spray water is evaporated.

In the simplest spray humidifying system the water is furnished from a constant source, such as city water. The spray may be of the direct atomizing type, in which, by means of properly designed nozzles, the water is broken up into fine particles, or of the target spray type, in which a fine stream of water under pressure impinges on a flat surface or target to be broken up into a spray. That part of the spray which is not evaporated is permitted to run to waste.

Any spray system in which water is run to waste must atomize as completely as possible to provide for the evaporation of the maximum amount of water. In order to produce fine atomization, small openings are

WINTER CONDITIONING

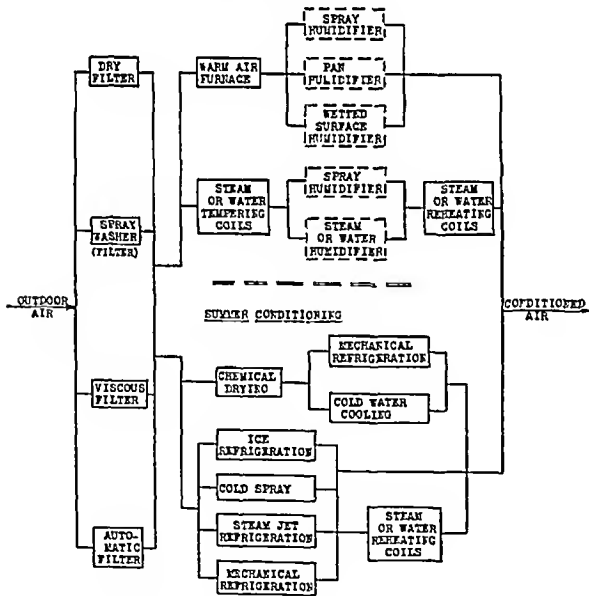

Fig 1—Essential steps in air conditioning

When no direct radiation is used as a source of heat the desired room temperature is maintained by air circulated over heated surfaces as in a furnace located elsewhere (indirect heating). A large part of the warmed air is recirculated within the building and only enough outdoor air added to provide "freshness" and freedom from odors. The reasons for this are obviously fuel economy and the size and initial cost of equipment.

Humidifying—Certain industrial processes demand a humid atmosphere the year round. As discussed in

necessary in the nozzles, which involve the danger of occasional clogging. Self-cleaning nozzles have been recently developed that materially reduce this hazard. Although all spray systems in which the water is not recirculated are wasteful of water, they are normally more economical to use in smaller installations. In large conditioning units requiring larger quantities of water the wastage may be excessive, and then it is more economical to install central humidifiers in which the water is recirculated.

Some atomizing units, in order to increase their moistening capacity, permit the spray to impinge against a heated surface, forcing its evaporation by that method, or the spray may be directed against a rotating disk, where it is mechanically separated into fine particles by the centrifugal action. One of the simplest methods of humidification is the direct introduction of steam into the air. Steam is little used for comfort conditioning because of the disagreeable odor usually accompanying it. In industrial applications, however, it is frequently used.

SUMMER CONDITIONING

Cooling—The phase of air conditioning that has been of greatest public interest in recent years is "cooling." In considering the comfort-cooling air it is perhaps best to think of cooling not as pure refrigeration.

Fig. 3—Compression refrigeration cycle (with water cooled condenser) applied to air conditioning

tion of the air but as the production of a cooling effect. This cooling effect on the human body may be produced in four ways, separately or in combination, by lowering the dry bulb temperature of the air, by dehumidifying the air, by evaporative cooling (which is functionally dependent on the humidity of the air) or by increasing the air movement. Lowering the dry bulb temperature alone may result in a cold, clammy feeling which is undesirable. Dehumidifying only, without cooling, produces hot, dry air that may also be undesirable. Moderate reduction in temperature combined with adequate dehumidification is usually considered best for comfort. The use of fans for alleviating discomfort in warm weather is a common practice but the higher air velocities usually created are objectionable in considerations of comfort.

If air is passed through a water spray in which the water is continually recirculated, the dry bulb temperature of the air will be lowered, for the air will give up a part of its heat in order to evaporate water. Under ideal conditions the air would continue to give up its heat to evaporate water until it became saturated with water vapor, so that at the same time that the dry bulb temperature is dropping the humidity of the air is increasing. In hot and dry climates this system of

evaporative cooling therefore proves most successful, but it is of no value in hot and humid climates.

In localities where water from deep wells or other sources is available at low temperatures in sufficient quantities, a cheap and simple method of cooling is provided. The air is simply passed over finned tube coils, similar to those used for heating work, through which the cold water is flowing. In many localities wells supply sulfurous waters which emit objectionable odors the concentration of which is increased when the water temperature rises after it is used for cooling purposes. This situation is ordinarily controlled in some sections by the use of a closed system associated with the return of the water to another underground water bed by means of a second well.

When cold water is not available, the water flowing through the coils may be cooled by the use of ice. The ice is stored in a bunker, and the water is sprayed over the ice to be cooled, the cooled water then passing through the coils. Ice cooling equipment usually costs less than that necessary for any other method except when well water alone is used. The hourly cost of operation, however, is fairly high, so that the use of ice is not economical when the season of operation is long.

Mechanical systems of refrigeration are most extensively used at the present time. A refrigerating machine is simply a mechanical device for the removal of heat from any system.

Certain liquids have the property of boiling at low temperatures. To assure this boiling, heat is commonly necessary. If air or water is passed over an evaporating substance, any heat required to complete the boiling process will be taken from the surrounding air (or medium) and the temperature of this air will be thereby lowered. Advantage of this fact (latent heat) is taken by the use of evaporators of some types.

A refrigerating machine for air conditioning consists of three essential parts: (1) a compressor, which with draws the gaseous refrigerant from (2) an evaporator or cooler and delivers it to (3) a condenser at a higher pressure and temperature so that its heat can be removed by air or water at ordinary temperatures. Thus the gas is condensed into a liquid and returns to the evaporator through an expansion valve, which allows the refrigerant to pass at such a rate as to maintain a predetermined temperature in the evaporator coil. Finally, in the evaporator the refrigerant boils, abstracting heat from the surrounding medium to produce refrigeration. Thus the system is completely closed and the same refrigerant, in small quantity, constantly recirculated in order to conserve it. The commoner refrigerants used for air conditioning are "Freon," carbon dioxide, "Carrene," "Dichlorine" and methyl chloride.

When refrigeration is employed, the air may be cooled by either of two methods using the direct or indirect expansion systems. In the direct expansion system, usually employed in smaller installations, the evaporator, which is a continuous bent tube finned similarly to a finned heating coil, is placed in direct contact with the air to be circulated. In the indirect expansion system the evaporator is used to cool water. The actual cooling of the air is brought about either by bringing the air into intimate contact with the cold water in spray chambers through which the air is circulated or by passing the cold water through finned tubes placed in the path of the air.

Another system of refrigeration, also operating on the principle that when evaporation takes place heat is absorbed, is known as the steam ejector system. This uses water as the refrigerant. Water under a vacuum vaporizes at low temperatures. Steam discharged, or ejected, from properly designed nozzles will produce a high vacuum. In the steam ejector system water is contained in an evaporator in which a high vacuum is maintained by ejection of steam. Because of the high vacuum, part of the water will flash into steam, the heat required for the vaporization coming from the rest of the water, which is cooled to a point dependent on the vacuum maintained. The water thus cooled is circulated for air cooling purposes in the same way as water cooled by ice or mechanical refrigeration. The steam jet system requires a large amount of condenser water, approximately three times that required for mechanical refrigeration. It also requires a supply of high pressure steam. In many cases the steam may be already available as when it is used for the production of power or process work. This system is economically justifiable when the steam and a copious supply of cheap water are available.

Dehumidifying—Dehumidification is an essential part of summer air conditioning. Moisture is precipitated when the air temperature is lowered to such a point that condensation takes place. The temperature at which condensation will take place is known as the dew point. The air under artificial conditions may be cooled to the dew point temperature either by maintaining a sufficiently low temperature in the evaporator coils over which the air passes or by cooling the spray water of the dehumidifier below the dew point of the air temperature.

According to the American Society of Heating and Ventilating Engineers' Guide,⁵ dehumidification may also be accomplished by absorption or adsorption of the moisture contained in the air. Absorption implies a change in the chemical or physical structure of the absorbing material in the process of dehydration, while adsorption is purely a surface action. Sulfuric acid is a common type of absorber. Adsorbers include lithium chloride, calcium chloride, silica gel, activated alumina, lamisilite, or any of the halides.

Silica gel is a colloidal form of silicon dioxide made from sodium silicate and acid. It is a hard glassy material with the appearance of clear quartz sand. The crystals are highly porous with the voids constituting 40 per cent by volume, although the pores are microscopic in size. Silica gel possesses the ability to adsorb a large quantity (up to 25 per cent of its own weight) of moisture from the air without any change in volume, structure or composition. After the silica gel has adsorbed moisture to the limit of its capacity, the water may be driven out by the application of heat. This cycle can be repeated indefinitely. In the process of adsorption heat is liberated, raising the temperature of the dry air. This heat may then be removed from the highly dehumidified air by extended surface cooling coils.

Silica gel units usually contain two compartments. Each compartment has several trays of adsorbing material supported on screens staggered so that a part of the air to be dehumidified passes through each bed of silica gel. While one compartment is adsorbing moisture the other is being reactivated by passing hot air from a gas burner through the material in order to dry

it. Dampers automatically shift the air flow from one compartment to the other at the end of each cycle of operation.

Activated alumina contains about 90 per cent of aluminum oxide, which will adsorb nearly 100 per cent of the vapor in the air and up to 10 per cent of the weight of the adsorbing material. The application is very similar to that of silica gel, the material is exposed to the air flow and, after reaching about 75 per cent saturation, is reactivated by driving off of the adsorbed moisture by the application of heat.

Calcium chloride is the cheapest and most widely used dehumidifying substance. However, its characteristics are such that relative humidities less than 30 per cent are difficult or impossible to obtain.

The cycle of operation for liquid adsorbers is fundamentally the same as for the solid adsorbers such as silica gel and activated alumina. In systems employing liquid adsorbers such as sodium, lithium or calcium chloride, the liquid adsorber is sprayed into the air. The adsorbing liquid, because of its lower vapor pressure, removes moisture from the air with which it is in contact. As in the solid adsorption systems, the removal of moisture is accompanied by a rise in temperature of the air. However, in this case the mass of liquid contained in the adsorber tends to keep down the rise in temperature.

As moisture is removed from the air, the concentration of the liquid adsorber is weakened so that its adsorbing capacity is reduced. Regeneration, or the driving off of the excess liquid, must be performed, a process similar to the driving off of the adsorbed liquid in the solid adsorber. However, with the liquid adsorber a definite condition of concentration may be maintained by continuously withdrawing a small portion of the liquid for intensive concentration and adding this concentrate to the mass of adsorbing liquid. The vapor pressure of the mass may be held fairly constant by this method of continuous regeneration, and the relative humidity of the leaving air will be held to a definite point.

Regeneration may be accomplished by raising the temperature of the adsorbing liquid to a point above the boiling point for the particular concentration. As the salts in the solution do not vaporize, they are not carried off in the boiling process, and the concentration is increased.

Air Circulation and Distribution—The objects of ventilation (the addition of outside fresh air), as agreed on by engineers and physiologists, are usually to remove odors, toxic substances, heat and moisture. There is no agreement among authorities as to how much fresh air must be introduced into a room for each person to give adequate ventilation. The lowest figure that will insure freedom from body odors is usually taken as 10 cubic feet per person per minute.

In order to provide this necessary ventilation, most air conditioning systems are arranged to recirculate a large part of the air from the occupied space and to take from outside the quantity necessary for "ventilation." The unit conditioner fan draws air through the conditioner and delivers it directly into any given room or space. The central conditioning fan discharges into a series of ducts which distribute the air to the rooms. The total quantity of air to be handled in either case depends on the amount of heat to be added or removed and the permissible temperature difference between the entering air supply and the desired room temperature.

This point of temperature differential between the air introduced and the room temperature is particularly important in summer cooling. A blast of icy air cools a room but may be objectionable and harmful to its occupants.

In comfort-conditioning, air is introduced into the room at temperatures varying from 5 to 30 degrees below the desired room temperature. Any of several methods may be adopted so that this air may be introduced into the occupied space without causing uncomfortable drafts. In order to remove moisture from the air by condensing it out, it may be necessary to cool it to a very low temperature and then reheat it to a suitable temperature. Reheating is often accomplished by mixing cool air with warm recirculated air just before introducing the air into the room.

If air is introduced into the room in a horizontal direction at a very high velocity, a great turbulence will be created that will mix the cold entering air with room air. High velocity nozzles or grilles are used to mix the air in this way at the ceiling height, whence it descends to the floor level owing to the greater density of the colder air. The limiting velocity that can be used in jets of this type is the velocity at which noticeable noise is created. It is possible, on the other hand, to use low entering velocities when there are a large number of inlets into the room, so that the distribution is uniform.

No matter what method is adopted for distribution of air, the air velocity in the occupied zone should not exceed 40 feet per minute in winter. Somewhat high air velocities are permissible during the summer period.

SMALLER AIR CONDITIONING UNITS

Three basic types of cooling units for smaller installations are now on the market, so-called self-contained, remote and central. The self-contained unit, commonly in the form of a cabinet, is placed in the room or enclosure to be serviced. Depending on its completeness, it controls one or more of the factors listed in the first part of this paper. The remote type has the refrigerating mechanism located at some remote place (closet or the like), from which the refrigerant is piped to cooling coils inside small cabinets, which may stand on the floor or be suspended from the ceiling or walls of the room to be cooled. The central type is a self-contained unit of larger capacity and usually located in the cellar, whence it transmits the conditioned air through a duct system to the rooms or spaces to be serviced.

COMMENT AND SUMMARY

This committee report briefly presents the mechanical requirements necessary to obtain suitable control of the following factors in air conditioning: temperature, humidity, air motion, air distribution, dust, bacteria, odors and toxic gases. It is emphasized that at the present time some commercial interests are stressing excessively low summer temperatures and are permitting high air velocities in air conditioned spaces, in comparison with outdoor conditions and in some cases are failing to provide adequate dehumidifying facility, a most important item in proper summer air conditioning. Much of the air conditioning now being installed is under the control of operators and proprietors who have such a complete misunderstanding of the requirements of the human body that it promotes discomfort and jeopardizes health for persons exposed to these "artificial climates."

FIRST ANNUAL SUMMARY OF FOURTH OF JULY INJURIES

SECOND SERIES

From 1903 to 1916 the American Medical Association presented annual summaries of injuries resulting from the celebration of the Fourth of July. Since 1916, which was the first year without a single case of tetanus, these reports have been discontinued. Unfortunately in recent years a considerable increase in the number of injuries has occurred, it seems expedient therefore to renew the annual reviews.

DEATHS

This year there were twenty deaths reported as due to the celebration of the Fourth of July with fireworks or firearms. The distribution by states is given in table 1. Burns from fireworks resulted in the death of seven youngsters, gunshots were responsible for the death of four boys, two men were drowned after their boat had been wrecked by an exploding firecracker, a toy cannon explosion killed a man, and a fire caused by explosion of a display of fireworks in a store caused the death of six women and girls.

TABLE 1—Deaths by States

State	Number of Deaths
California	1
Florida	1
Idaho	6
Maryland	1
Massachusetts	2
New Jersey	1
New York	3
Ohio	1
Rhode Island	1
Texas	1
Utah	2

The worst single accident of the year occurred in Nampa, Idaho, on July 1. A shelf of fireworks in a drug store caught fire and exploded with thirty people in close proximity. This tragic display resulted in the death of six and the serious injury of several others. Another strange accident occurred, according to newspaper reports, on Cayuga Lake, N. Y. According to the story told to authorities, three men started celebrating by shooting cherry bombs and firecrackers along the shore of the lake, finally pushing out into the lake in a rowboat. A large firecracker exploded under the boat, tearing a hole in it, and two of the three men were drowned.

TETANUS

Only two cases of tetanus were reported this year, one in Minnesota and one in Ohio. Both patients recovered. The small number is due, however, not so much to lack of opportunity for tetanus to occur as to the splendid cooperation of physicians, police, hospitals and first aid units in giving tetanus antitoxin immediately following an injury. Evidently all are thoroughly cognizant of the necessity for giving tetanus antitoxin even in the presence of what appear to be relatively slight injuries.

INJURIES

Table 2 lists the number of injuries by type and cause. The total number of injuries recorded for this Fourth of July celebration numbered 7,205. Obviously this figure errs on the side of underestimation. Thus, although 4,292 questionnaires were sent out to hospitals

requesting them to list the Fourth of July injuries treated, only 2,463 were returned. In addition, doubtless more injuries were treated in first aid stations or by physicians in their offices than were treated in hospitals. The total number of injuries, therefore, was probably far in excess of those which were actually recorded.

Comparative figures with other years since 1916 are not available and hence any attempted contrast at this time would be futile. Attention, however, should be drawn to the fact that in 1916, the last year of the previous annual reports, there was not a single case of tetanus reported.

Study of the table in the light of available information discloses several important points. Thus New Jersey, which only this year received the benefit of a state law against fireworks, had only seventy-two injuries, while Pennsylvania with only 24 times the population (1930 census) and without such a state law had 991 injuries. In fact, many of the individual reports from New Jersey indicated the "bootlegging" of fireworks across the state line from Pennsylvania, and so the latter state may well be considered to have contributed materially to those injuries from fireworks which actually occurred in New Jersey. Many individual hospital questionnaires from New Jersey stated voluntarily that this year for the first time their hospitals treated no injuries from fireworks, in contrast to previous records of from 100 to 150.

Michigan, which also possesses a state law against fireworks, had only 190 injuries, while Illinois without such a state law, and a population approximately 1.5 times as large, had 485 injuries.

The Southern states, as a group, reported few injuries from fireworks. This is due principally, as was mentioned on numerous questionnaires, to the fact that in most regions of the South there is no fireworks celebration of the Fourth of July. Fireworks, however, are used at Christmas time, and many of the hospitals reported that serious injuries frequently occur at that time. (An example is that of Dec. 24, 1936, at Asheville, N. C., where a preview of the Nampa, Idaho, tragedy occurred. A fireworks display in a downtown store exploded, killing several people and burning others.)

In spite of the fact that several of the principal cities of the country have ordinances against the sale of fireworks inside their corporate limits, most of them had a large number of injuries. Table 3 lists the injuries for several of them and their rates per hundred thousand. Again it is obvious that local regulations are only slightly effective in preventing such injuries, since the forbidden fireworks can easily be purchased outside the city limits and brought in by automobile.

SERIOUS INJURIES

In addition to the deaths and cases of tetanus, newspaper clippings and hospital questionnaires recorded a considerable number of persons, mostly children, so seriously injured that they will bear the scars of their experience for the rest of their days. There were many bad burns, chiefly from sparklers, in many instances requiring prolonged and persistent hospital care and often resulting in permanent scarring. In one serious accident in Jamaica, N. Y., according to newspaper clippings, three high school students were seriously injured by experimenting with certain chemicals for celebration purposes. Both hands of one boy were amputated and one hand of another. The eye injuries

from the standpoint of numbers and permanent disability were perhaps the most appalling. Table 2 lists them by state but can give no true picture of their individual significance.

TABLE 2—Types and Causes of Injuries

COMMENT

In spite of the apparent effectiveness of the campaign by the American Medical Association which terminated twenty-one years ago, there has been an evident increase in the misdirected celebration of Independence Day by dangerous fireworks. This increase has occurred in

spite of the fact that municipalities and good citizens generally have continued their efforts to regulate the sale and use of fireworks. Part of the increase may be due to lack of social consciousness of this dangerous activity. Part seems to be due to the fact that in spite of legal regulations the almost universal use of the automobile has made city limits and even state lines no longer any material barrier to the transportation of much illegal material. All of the previous reports of THE JOURNAL on this subject stated that "the responsibility clearly rests with city governments." Evidently this no longer holds strictly true, since city governments cannot enforce regulations outside their limits and transportation is now too easy.

Special Clinical Article

A SIX YEAR STUDY OF THE CLINICAL EFFICACY OF VARIOUS DIGITALIS PREPARATIONS

CLINICAL LECTURE AT ATLANTIC CITY SESSION

WILLIAM D. STROUD, M.D.

AND

JOSEPH B. VANDER VEER, M.D.

PHILADELPHIA

Although an excellent book on digitalis has recently been published¹ and numerous papers have been written concerning the efficacy of various glucosides of digitalis,² confusion still exists in the mind of the average practitioner as to the indications for the use of digitalis, the best method of its administration and the most efficient type of preparation to be used. Unfortunately, from time to time various articles with conflicting opinions as to the indications and contraindications for digitalis have appeared in the medical periodicals. Furthermore, the problem has been rendered more difficult by the more or less generalized change from the tincture to use of the powdered leaves in tablet, capsule or pill form, the introduction of the term cat unit³ in expressing biologic potency and dose and the pressure of salesmanship of the manufacturing drug firms as to the special merits of their respective preparations.

The purpose of the present paper is (1) to emphasize a few of the main indications and contraindications for digitalis, (2) to review briefly its mode of action, the dose and methods of administration and (3) to discuss the therapeutic merit of several special preparations of the isolated digitalis principles (glucosides), compared with whole leaf preparations, as determined in a clinical study during the last six years.

Read in the General Scientific Meetings at the Eighty Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 7, 1937.

This work was done through the Rohmette Foundation of the University of Pennsylvania and the W. W. Stroud Jr. Fellowship in Cardiology of the Pennsylvania Hospital.

3. A cat unit represents the minimum amount of digitalis which is required per kilogram of body weight to kill a cat when injected slowly and continuously intravenously. It represents 1½ grains (0.1 Gm.) of powdered leaves or 1 cc. (15 minims) of tincture.

INDICATIONS

More than a hundred years ago digitalis lost favor as a therapeutic agent because of its inability to slow tachycardias due to fever, and yet today many physicians prescribe digitalis with the hope of slowing rapid heart action due to fever, thyrotoxicosis, hypersensitivity of the sympathetic nervous system and peripheral circulatory failure. This practice is especially common in connection with surgical procedures, digitalis being given postoperatively in some places almost as a matter of routine.

Needless to say, digitalis proves of no advantage in the treatment of such conditions except in certain cases of thyrotoxicosis accompanied by cardiac disease of different etiology (such as a rheumatic valvular defect associated with congestive heart failure) or in cases of pneumonia complicated with auricular fibrillation or auricular flutter. As shown in the study of pneumonia at Bellevue Hospital,⁴ digitalis when indicated in the treatment of this disease should be given only in divided doses, since massive doses may prove distinctly dangerous.

During the last two decades, several investigators have called attention to the differential diagnosis between circulatory failure due to disease of the heart and circulatory failure resulting from collapse of the peripheral vascular system. As described by Harrison,⁵ "The clinical picture of peripheral circulatory failure (shock, collapse) is characterized by weakness as the chief subjective phenomenon, and by ashen pallor, cold clammy skin, tachycardia, weakness of the pulse, diminution in systolic pressure." In emergencies of this character, digitalis proves of but little—if any—benefit, and, through recognition of this fact, the formerly rather prevalent procedure of administering this drug postoperatively (in ridiculously small doses) to patients with circulatory failure of peripheral origin has been abandoned. Digitalis is seldom indicated in emergencies unless there is definite evidence of right or left ventricular failure, and then in order to secure clinical benefit within a few hours large doses are necessary.

Although some clinicians still question the statement that proper digitalization improves tonicity and contractility of the myocardium, it is our opinion, as stated in a previous publication by one of us,⁷ that the therapeutic benefit of digitalis is effected in one or all of three ways, as follows:

1. By slowing the heart rate, that is, by lessening the number of ventricular systoles per minute, the diastolic period is lengthened, whereby ventricular filling is rendered more complete, and the heart muscle fibers are afforded more rest, and as a consequence, there may result a greater expulsion of blood into the circulation with each systole.

2. By increasing the cardiac tone, thereby relieving or preventing dilatation of the heart chambers beyond the physiologic limit, the optimum cardiac output is made possible. When the length of the heart muscle fibers is increased beyond a certain limit, the cardiac output is decreased and "heart failure" is believed to result. Restoration of the fibers to a

shorter length is a factor in bringing about an increase in cardiac output, with the possible return of circulatory efficiency.

3 Through increase of the extent of ventricular contraction, there tends to be an increase in cardiac output when heart failure is present.

If the effects mentioned are to be expected from digitalization, the question arises as to when in the course of progressive cardiovascular disease the patient should be digitalized. Christian⁸ expressed the opinion that, as soon as a diagnosis has been made of cardiovascular disease (particularly hypertension or valvular disease) which may place an additional burden on the myocardium, the patient should be digitalized and digitalization should be maintained throughout the remainder of life. On the other hand, Harrison and Leonard⁹ (in a study of dogs) and Burwell, Neighbors and Regen¹⁰ (in a study of human beings) found that a reduction in output of the normal heart occurs with full digitalization. Certain studies¹¹ suggest that if the heart is normal or has perhaps a slight degree of dilatation and hypertrophy, digitalis lessens the efficiency of the heart muscle and also decreases the flow in the coronary arteries. The same studies indicate that there may be a stage in the progressive dilatation and hypertrophy of a laboring myocardium at which digitalis seems to improve the efficiency of the heart muscle and also the flow from the coronary sinus into the heart. Hypertrophy and dilatation unchecked tend toward a point where a certain optimal length of the fibers of the heart muscle is exceeded and a decrease in cardiac output results (described by Starling¹² as the law of the heart), with gradual or sudden development of signs of heart failure. On the basis of this hypothesis, it is the physician's responsibility to estimate—through the patient's history, the physical appearances, electrocardiographic and x-ray studies and his knowledge of the usual progression of the various cardiovascular diseases—just when the stage has been reached (as shown in the accompanying illustration) at which digitalization will preserve optimum cardiac output through increase of tonicity and extent of ventricular contraction.¹³

It is our belief, therefore, that in the treatment of patients with progressive chronic cardiovascular disease digitalization should not be started as a matter of routine at the time of diagnosis but when, in the opinion of the physician, the pathologic processes have progressed to a point where digitalization may increase ventricular output and improve coronary flow.

METHOD OF ADMINISTRATION

The vast majority of patients can take digitalis by mouth. Although the emetic action of digitalis is not due to a direct irritant action on the gastric mucosa but is a reflex effect from the direct action of the drug on the heart (the impulses passing from the heart to the vomiting center in the medulla), occasionally psychic vomiting due to knowledge of the toxic gastric effects is encountered. Intravenous digitalis therapy is seldom indicated. Subcutaneous administration is necessary

only in the presence of vomiting or unconsciousness or when the patient is unable to swallow. Rectal administration is seldom necessary.

It is generally admitted by physicians with experience in both methods of administration that tablets, capsules or pills of powdered digitalis leaves are much more practical than the tincture. In the first place, such preparations seem to maintain their potency better than the tincture, and, in the second place, the dosage is much more accurate, since even with the standard minim dropper the patient is apt to miscount the number of drops. The impossibility of accurate dosage in the absence of a standard minim dropper is well known to all who have tested the average medicine dropper sup-

Stage at which digitalization will preserve the optimum cardiac output.

plied by the drug store.¹⁴ Furthermore it is more convenient to carry tablets, capsules or pills than a bottle of the tincture.

According to our experience the large dose method of administering digitalis is seldom necessary. In emergency cases when there is no vomiting, full digitalization can be accomplished with tablets of standardized digitalis (or their equivalent in glucoside preparations) when given by mouth, in from 4½ to 6 grain (0.3 to 0.4 Gm) doses every six hours, within twenty-four to thirty-six hours. In the average case of congestive heart failure, complete digitalization can be accomplished in from forty-eight to seventy-two hours by administration of 3 grains (0.2 Gm) of digitalis three times a day. For an ambulatory patient with heart failure of mild or moderate degree, full digitalization can be accomplished for six or seven days by a 1½ grain (0.1 Gm) tablet given three times a day. After digitalization it has been our experience that the average maintenance dose is about 1½ grains daily. Of course some patients may require slightly larger doses,

14 A dose in drops from an ordinary dropper has from two to three times the number of drops as the same amount measured in minims.

while in other instances the maximum effect is maintained by means of considerably smaller doses, even as little as one-half grain (0.03 Gm) daily.

In summary then, 1½ grains of a properly standardized tablet, capsule or pill of digitalis leaves is equivalent to 15 minims (1 cc), or approximately 45 drops, of a well standardized tincture. In general physicians are finding the tablet, capsule or pill a much more convenient form for administering digitalis than the old fashioned tincture. It is necessary to use between 18 and 30 grains (1 and 2 Gm) of digitalis to digitalize fully the average adult patient. Except in emergencies

tions made from powdered whole digitalis leaves has logically evolved from the stability, accuracy of dosage and satisfactory clinical results of this form of the drug. In addition to whole leaf products, many "purified" preparations containing one or more of the glucosides of digitalis are now available. It is possible that the necessity for bio-assay may be obviated with these preparations, and clinically they should be reliable and efficient. The great variation in their equivalent doses, however, has added confusion to the problem of digitalizing the patient and establishing a maintenance dose.

The clinical comparison of different preparations of digitalis is a difficult procedure. The digitalizing dose and the daily maintenance dose of one preparation may be sufficient to maintain circulatory efficiency in a given patient, while the same dose of another preparation may, while satisfactory, hold the patient continuously closer to toxic manifestations. In other words, "in making such a study it must be remembered that there exists in a majority of patients with established auricular fibrillation a fairly wide margin between the minimum dosage necessary for optimum digitalization and the maximum dosage which can be tolerated without the incidence of toxic effects."²

During the past six years we have conducted a clinical study using several preparations of digitalis.¹³ The data on fifty-six of a large number of patients observed during this period are satisfactory for analysis. Thirty of the patients had organic heart disease with chronic auricular fibrillation and were taking digitalis when they came under observation. All these patients were observed for two or more years and were ambulatory, and practically all developed rapid ventricular rates with pulse deficit if digitalis was omitted. Seventeen were observed for three or more years and eleven for over four years. Twenty-six patients had never received a preparation of digitalis before coming under observation because of heart failure. All were hospitalized, and the digitalizing dose of a given preparation was determined by clinical trial. Seventeen patients had auricular fibrillation, three had auricular flutter and in six normal sinus rhythm was present.

Our first study was with American Heart Association whole leaf tablets of digitalis as prepared by Gold at Cornell University, the 'tabloids' of whole leaf digitalis prepared by Burroughs, Wellcome and Company, and Digalen a preparation of purified glucosides supplied by Hoffman-LaRoche Inc. Ambulatory patients with established auricular fibrillation, twenty-five in number, were selected from the adult heart clinic of the Pennsylvania Hospital and divided into three groups similar as to age, and degree of circulatory efficiency. The clinical course of the three groups was followed for nine months on the three respective preparations of digitalis. During the subsequent six months, four of the nine members of the group which had previously received the preparation containing only the glucosides were changed to the commercial whole leaf tablet, and the others were given the American Heart Association product. Five of the seven patients originally given the commercial whole leaf product were changed to the glucoside preparation, and the remainder were given the A. H. A. product, six members of the group started on the A. H. A. product were then placed on the glucoside tablet, and three were given the commercial whole leaf product. Each patient reported to the cardiac clinic at intervals of from one to four weeks for a check up of symptoms and a physical examination which included a vital capacity determination. Orthodiagraphic and electrocardiographic studies were made every three or four

our usual routine is to give the patient 1½ grains of powdered digitalis four times a day (6 grains daily) for three days. Thus with a total of 18 grains we approach full digitalization with little danger of toxic symptoms. From then on the daily dose is determined by the condition of the patient's circulation or the development of toxic symptoms. The average daily maintenance dose of digitalis is between one-half grain and 3 grains a day.

CHOICE OF PREPARATION

"The proof or disproof of a drug's efficacy rests finally on the test in patients." This statement of Sir Thomas Lewis applies especially to digitalis preparations. A drug of the value and having the widespread use of digitalis deserves the greatest consideration from the practical clinical standpoint. In a given case the therapeutic efficiency may largely depend on a sufficient but nontoxic dose. The present popularity of prepara-

¹³ The following physicians assisted in this study at various times: Albert W. Bromer, J. Roswell Gallagher, Norman I. Shamway, D. L. W. Leis, Noble F. Crandall and Dewitt W. Demmick.

months During our study of more than eighteen months, no striking difference was observed in the general clinical picture, including the ability to work of the members of the three groups ¹⁶

The final check up of the original twenty-five patients with whom the study was begun in 1931 is of interest Twelve patients are still living, and eleven of these are still regular attendants at the cardiac clinic Of ten patients with marked cardiac enlargement, only three are living Six of eleven patients with moderate cardiac enlargement are alive, and of four with slight enlargement three are in relatively good health and working

Our second study was with verodigen—a gitalin glucoside of digitalis Five patients with established auricular fibrillation and one patient with auricular flutter, all previously untreated with digitalis, were digitalized with this drug, as were two patients with regular sinus rhythm and advanced congestive heart failure Of the ambulatory patients whose established auricular fibrillation had previously been controlled with whole leaf digitalis preparations or digalen, four-

teen were given verodigen Clinically we found 1/240 grain of verodigen to be equivalent to one cat unit (approximately 1 1/2 grains of powdered digitalis), and the total dose necessary for digitalization from 1/20 to 1/12 grain administered over five or six days The most frequent adequate maintenance dose of verodigen was 1/240 grain daily ¹⁶
For about one year our study was concerned with digitaline (Nativelle) Twelve patients with heart disease who had previously received no preparation of digitalis were digitalized by this glucoside Eighteen patients whose established auricular fibrillation had previously been controlled by one or more preparations of digitalis were given digitalin The average period of observation for this group was ten and one-half months The total dose necessary for digitalization varied from 1/50 to 1/30 grain when administered over five or six days The most frequent adequate maintenance dose was 1/600 grain daily
Our most recent study was made with Digoxin ¹⁷ It was carried out in a similar manner, and twenty-seven

patients were observed Six of them had never previously received digitalis in any form, and the remaining twenty-one had been maintained with one or more other preparations of digitalis The average period of observation of the latter group was eight and one-half months The most frequent satisfactory maintenance dose of this product was approximately 1/160 grain daily, and we feel that this dose is clinically the equivalent of one cat unit of standardized digitalis leaves

The following case presents an example of the type of ambulatory patient observed The data recorded are a portion of those obtained during a four and one-half year period of observation while the patient was receiving five different preparations of digitalis The effect of stopping all medication for a few weeks is well shown The gradually decreasing vital capacity is of interest Clinically there was no change in the patient's condition during the study

S F, a Jew, aged 32, complained of rapid heart action of three months' duration, with fatigue, dyspnea on exertion and cough, on his first visit to the Cardiac Clinic of the Pennsylvania Hospital, in June 1931 At the age of 15 years he had been told that he had a heart murmur, however, he had been in excellent health and had been very active physically previous to 1931 Physical examination revealed cardiac enlargement, mitral stenosis and insufficiency and auricular fibrillation, without any signs of congestive failure Since 1931 he had been taking digitalis regularly

The cardiovascular diagnosis was as follows A, unknown (tonsillitis), B, cardiac enlargement, mitral stenosis and insufficiency, C, auricular fibrillation, D, class 2a The clinical course is shown in table 1

The data in table 2 show the effect of increasing or decreasing the maintenance dose of a digitalis preparation in treating a condition previously well controlled on the same preparation

COMMENT

The results of a clinical study of this type must be interpreted in the light of the normal variations and the personal element involved It is essential that a large number of patients be observed over a considerable period of time (One of us has personally observed all the patients included in this study) The natural history of disease must be considered, and gradual progression of the pathologic lesion is to be expected in many cases Complications, especially infectious or embolic, may alter the course of the disease It is wise to include patients who have never previously received any preparation of digitalis Patients with established auricular fibrillation and inherently rapid ventricular rates are the most satisfactory when one is judging the digitalizing and the maintenance dose of a given preparation

There seems to be little relation between the weight of the patient and these doses For practical purposes the weight need not be considered The important point is to give the patient a sufficient amount of the preparation, avoiding overdoses In a given patient this amount can be determined only by clinical trial It should be remembered that the more severe the heart damage the less the margin of safety in using digitalis preparations With a bad myocardium, toxic rhythms (premature beats, coupled rhythm and ventricular tachycardia) may appear before nausea and vomiting or other signs of an overdose

The release of digitalis preparations or other similarly acting drugs before the dosage and efficacy are determined by adequate clinical trial is to be deprecated

16 Tr Am Climat. & Clin A 51 51 (Oct) 1935
17 The manufacturers of verodigen—Merek & Co—and of digitaline (Nativelle)—E Fougera & Co Inc.—claim that their preparations are pure stable crystallized glucosides isolated from the leaves of digitalis purpurea and the manufacturers of digoxin—Burroughs Wellcome & Co—claim that it is the same type of glucoside isolated from the leaves of digitalis lanata If these claims are true these three preparations should keep indefinitely and the dose can be determined by weight without the necessity of animal bioassays

The dosage determined by biologic assay may have more or less than the predicted potency when the drug is administered orally to man. Experience with one product in which the strength for man was three times that predicted by the biologic assay² has led us to be cautious in evaluating these products on the basis of animal experimentation.

A better result from a given product of digitalis may be due to a relatively greater amount of potent substance rather than to a greater efficacy of the product as compared to some other preparation. This fact probably accounts for much of the improvement seen in patients after they change from one preparation to another.

It has long been known that potent preparations of digitalis produce nausea and vomiting if given in sufficient doses. We have observed these symptoms with all glucoside preparations studied. Other manifestations of toxicity, such as coupling of premature beats, were also noted in all instances. There was no evidence that digitalization was effected more rapidly with any

TABLE 3—Doses of Various Preparations

Name of Preparation	One Cat Unit Grains	Full Digitalization, Grains
American Heart Association whole leaf tablet	1½	18 30
Burroughs, Wellcome & Co whole leaf tablet	1½	18 30
Digalen	1½	18 30
Verodigen	1/240	1/20 1/12
Digitalin (Nativelle)	1/600	1/50 1/30
Digoxin	1/160	1/13 1/8

of the glucoside preparations than with digitalis leaves, when given by mouth. After cessation of the drug in a fully digitalized patient, "digitalis effects" seemed to persist for about the same length of time (from three to six weeks) with the various preparations.

All the glucoside preparations tested were uniformly potent and stable. The clinical results were similar and equal to those of standardized digitalis leaves when given in sufficient doses, but they were in no way superior. If these preparations are pure substances, as is claimed, it would seem safe to dispense with biologic assay, which should reduce the cost of manufacture considerably.

It is possible that in the future the chemical isolation and standardization of digitalis glucosides may be the method of choice in producing preparations for clinical use. It seems logical, however, if all the glucosides are potent when given orally to man, that the whole leaf which contains all these substances may be preferable clinically.

SUMMARY AND CONCLUSIONS

The clinical equivalent of approximately 1 cat unit of the preparations studied is listed in table 3. This is the average daily maintenance dose. The second column contains the average full digitalization dose given over a period of from three to six days.

All the preparations were uniformly potent and efficacious and produced similar effects when given orally in equivalent doses.

There was no evidence that the glucoside preparations, when given by mouth, were quicker in action, more efficient, more prolonged in action or less toxic than standardized whole digitalis leaves.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT:

THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE VALUE OF ASSISTANCE RENDERED IN THE PREPARATION OF THIS REPORT BY DRs. GEORGE M. COATES, LEE W. DEAN, EDMUND P. FOWLER, AUSTIN A. HADEN, ISAAC H. JONES, DOUGLAS MACFARLAN, HORACE NEWHART, BURT R. SHURLY AND WILLIAM P. WHERRY.

HOWARD A. CARTER, Secretary

PURPOSE OF AUDIOMETERS

A clinical audiometer is an instrument for measuring the acuity and range of hearing.

TENTATIVE MINIMUM REQUIREMENTS FOR ACCEPTABLE AUDIOMETERS

A. Specifications—

1. Audiometers shall produce vibration at frequencies within hearing range (approximately 128 to 8,192 cycles, or higher, per second). They shall be equipped for testing both air and bone conduction.

2. Frequencies (a) Continuous frequencies (sweep) from 128 to 8,192 (or higher, for example, to 16,000) cycles per second.

(b) Fixed frequencies from 128 to 8,192 cycles per second. If discrete frequency steps are provided, the tones shall be 128, 256, 512, 1,024, 2,048, 4,096, 8,192 cycles per second. Numerical annotations to be used designate pitch.

(c) The limits of tolerable frequency variation shall be not more than ± 5 per cent at all frequencies. Dials shall be marked so that frequencies may be identified readily.

3. Attenuation. Audiometers shall be calibrated in decibels, with 5 decibels per step or less. In no case should more than 5 decibel steps integrals be used. Tolerant limits to be within $\pm 1\frac{1}{2}$ decibel per 5 decibels steps and ± 5 decibels cumulative at any portion of the intensity range. Dials shall be easily read. The term "percentage hearing" shall not be used, but hearing losses shall be reported in decibels units loss.

4. Range of Intensity. The intensity range of the test tones above the normal threshold shall be at least that as follows:

Test Tone Cycles per Second	Intensity Range Decibels
128	60
256	80
512	85
1,024	90
2,048	90
4,096	90
8,192	80

5. Wave Form. The purity of the tone in the air conduction receiver shall be such that the harmonics at any particular frequency shall be at a level not less than 40 db below the fundamental tone or that other accessory noises (such as the line hum, click of interrupting switches, etc.) shall in any way interfere with the test tone.

6. For a bone conduction receiver, the sensation level of the sound reaching the tympanum through the auditory meatus shall be at least 5 decibels below the level generated by bone conduction at all test frequencies as judged by a normal ear, when the bone conduction receiver is placed on the mastoid region.

7. Power Supply. Either alternating or direct current, alternating-direct current or battery.

8. Ruggedness of construction to stand reasonable usage. Use of readily obtainable and replaceable parts.

9. Uniformity in calibration in decibels.

10. Advisability of the selection of a central, disinterested agency for reporting on physical characteristics of various audiometers.

11. Advisability of manufacturers assuring servicing.

B. Audiogram or Auditory Chart—

(To be adopted later when a more definite consensus of opinion develops.)

C. Definition of Threshold of Hearing.—The threshold of hearing is the audiometer setting corresponding to the lowest

intensity at which the person being tested is able to indicate correctly more than half the time that he is hearing

D Marketing and Advertising—Rules of the Council on Physical Therapy shall be adhered to by manufacturers of acceptable audiometers

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

PANTOPON "ROCHE" II

PANTOPON "ROCHE" WAS ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN NEW AND NONOFFICIAL REMEDIES IN 1915 AS PRODUCING ESSENTIALLY THE EFFECTS OF OPIUM, BUT BEING DEVOID OF ITS EXTRACTIVES IT MAY BE USED HYPODERMICALLY. IN 1931 IT WAS OMITTED FROM NEW AND NONOFFICIAL REMEDIES BECAUSE OF EXTRAVAGANT AND UNWARRANTED ADVERTISING CLAIMS OF THE DISTRIBUTOR. SINCE THAT TIME THE COUNCIL'S ATTENTION HAS BEEN CALLED TO PROMOTIONAL MATERIAL ISSUED BY HOFFMANN LA ROCHE INC WHICH APPEARED TO REPEAT THE OBJECTIONABLE CLAIMS. THE COUNCIL RECENTLY CONSIDERED SUCH A CIRCULAR AND POINTED OUT TO THE FIRM ERRONEOUS STATEMENTS CONCERNING THE COMPARATIVE CONTENT OF PANTOPON IN RELATION TO MORPHINE SULFATE. THE FIRM AFTER RECEIVING A STATEMENT OF THE COUNCIL'S CONSIDERATION REPLIED THAT THE ERRONEOUS STATEMENTS WERE MISTAKES WHICH WOULD NOT OCCUR AGAIN AND ASKED THAT THE REPORT OF THE COUNCIL'S CONSIDERATION BE WITHHELD FROM PUBLICATION. THE FIRM INTIMATED THAT IT WOULD RESUBMIT THE PRODUCT FOR RECONSIDERATION. IN THE MEANTIME THERE CAME TO THE REFERENCE'S ATTENTION A STUDY BY DRS J M HAYMAN JR AND HERBERT FOX WHICH CONFIRMS THE COUNCIL'S CONTENTIONS CONCERNING PANTOPON. THE COUNCIL CONSIDERED THIS REPORT AND AUTHORIZES PUBLICATION.

THE COUNCIL WISHES AT THIS TIME TO EXPRESS ITS APPRECIATION TO DRS HAYMAN AND FOX FOR MAKING THE FOLLOWING REPORT AVAILABLE

PAUL NICHOLAS LEECH Secretary

COMPARISON OF THE ANALGESIC ACTION OF PANTOPON AND MORPHINE SULFATE

J M HAYMAN JR, MD
AND
HERBERT FOX, MD
CLEVELAND

Asserting that the action of opium possesses certain advantages over that of morphine, Professor Sahli induced Dr Scharges of the Hoffmann-La Roche Laboratories to prepare a mixture of the hydrochlorides of all the alkaloids of opium, in the proportions occurring naturally, in a form suitable for hypodermic injection. This preparation was called Pantopon, and Sahli¹ in 1909 reported its satisfactory use but without giving any details of its supposed superiority over morphine. Since this paper many references to Pantopon have appeared in the literature, but there is no agreement regarding the cause of its reputed superiority over morphine. It is said to produce less nausea and vomiting and to give less respiratory depression,² presumably owing chiefly to the narcotin present. It is advocated for the relief of renal colic³ because of the relaxation of ureteral tonus produced by the papaverine present. Macht and his associates, in a study of cutaneous pain, reported that Pantopon had a greater analgesic effect than an equivalent dose of morphine,⁴ while Winternitz⁵ concluded that the residual alkaloids contributed little to the analgesic action of opium. Barlow,⁶ in a study of the tranquilizing potency of morphine and other opium

alkaloids for rats, obtained no evidence "that would indicate any significant activity on the part of the residual opium alkaloids contained in Pantopon." Eggles-ton and Hatcher⁷ found that in dogs Pantopon was actually slightly more emetic than could be accounted for by the morphine content.

The usual dose of Pantopon, one-third grain (0.0216 Gm), costs the hospital twice as much as morphine sulfate, one-fourth grain (0.0162 Gm). Since Pantopon is said to contain 50 per cent of morphine hydrochloride,⁸ it might be expected that as far as its morphine content is concerned the effect of one-third grain of Pantopon would be equivalent to one-sixth grain (0.0108 Gm) of morphine sulfate. But one-third grain of Pantopon contains one-sixth grain of anhydrous morphine hydrochloride, while U S P morphine sulfate contains five molecules of water of crystallization. Therefore, on a basis of morphine alkaloid there is only about one twenty-fifth grain (0.0026 Gm) less morphine in one-third grain (0.0216 Gm) of Pantopon than in one-fourth grain (0.0162 Gm) of morphine sulfate.

We have attempted to determine whether any differences could be detected in the analgesic effects of Pantopon and morphine, either beneficial or deleterious, when these were given as objectively as possible. The plan of the experiment was to administer the drugs in varying order to patients requiring morphine, in such a manner that neither the patient nor the observer would know which drug had been given. Information was sought on two questions: (1) whether the method could detect differences in the effect of dosages of one-sixth grain (0.0108 Gm) and one-fourth grain (0.0162 Gm) of morphine sulfate, and (2) whether the effect of Pantopon differed from either dosage more than the two dosages of morphine sulfate differed between themselves. Since Pantopon tablets are brownish biconvex disks, while morphine sulfate tablets are white and flat, Prof E D Davy of the School of Pharmacy of Western Reserve University was kind enough to color tablets of morphine sulfate for us and to run Pantopon through the same tablet machine so that they were of the same shape. The tablets as used were indistinguishable in appearance. Only one of the several nurses who administered them thought she could distinguish the Pantopon by its less ready solubility. All doses were ordered by number and given hypodermically. The results were recorded on special forms by the nurse or the house officer. The drug was considered to have given complete relief if the patient was relieved of pain or asleep in half an hour, moderate relief if effective in from one-half to one hour, and no relief if the patient was still complaining or uncomfortable at the end of one hour. The effectiveness of morphine sulfate one-sixth grain (0.0108 Gm), morphine sulfate one-fourth grain (0.0162 Gm) and Pantopon one-third grain (0.0216 Gm) was compared for the relief of postoperative pain and discomfort, the pain of renal colic, pleurisy, peritonitis, facial herpes and other conditions, and for the restlessness of cardiac dyspnea and other conditions. The distribution of doses is given in the accompanying table.

It will be noted that the analgesic efficiency of one-third grain of Pantopon is practically the same as that of one-fourth grain of morphine sulfate, or, in other words, that it is not materially greater than that of its

7 Eggles-ton Cary and Hatcher, R A J Pharmacol & Exper Therap 7 225 (Oct.) 1915

8 New and Nonofficial Remedies 1930 Chicago American Medical Association

morphine content Nausea, or nausea and vomiting, which had not been present before the use of any narcotic, occurred in one patient after one-sixth grain of morphine sulfate and in three patients after Pantopon. There was no apparent difference in the degree of respiratory depression with the three preparations. Detailed study of pulse and blood pressure changes were not made.

A striking point in the whole study was the variability of relief afforded the same patient at different times.

Distribution of Doses

	Morphine Sulfate 1/8 Grain	Morphine Sulfate 1/4 Grain	Pantopon 1/4 Grain
Postoperative	53	44	48
Pain	19	28	22
Restlessness	11	5	14
Degree of relief according to the criteria used			
	Doses	Relief	
		Complete	Moderate None
Morph sulf 1/8 grain	83	38 (45.7%)	36 9
Morph sulf 1/4 grain	77	46 (59.7%)	26 5
Pantopon 1/4 grain	84	50 (59.5%)	29 5

by the same drug as well as by the different drugs at different times. This has impressed us with the fact that the factors contributing to the condition of a patient are so complex and so variable from time to time that assay of the relative merits of two drugs is extremely uncertain unless the one shows a consistent superiority under all conditions of administration.

CONCLUSION

Blind tests confirmed that morphine sulfate one-fourth grain is more likely to give relief from pain than morphine sulfate one-sixth grain and apparently not materially more likely to produce nausea. No indications have been obtained that Pantopon one-third grain possesses any advantages over morphine sulfate one-fourth grain.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
FRANKLIN C. BING Secretary

Vitamin D Milk Produced by Feeding Cows Irradiated Yeast

In 1929 Wachtel¹ reported that the feeding of irradiated dried yeast to cows resulted in the secretion of vitamin D in the milk. This report was confirmed and amplified by the observations of Hart and Steenbock and their associates² at the University of Wisconsin. Later work has revealed the factors concerned in the feeding of irradiated dried yeast in order that a milk of uniform vitamin D potency might be produced. The yeast must be fed two or more times daily rather than all at one feeding. The amounts to be fed depend on the amount of milk secreted. High producing cows are more efficient than low producing cows in transferring vitamin D from the food to the milk. Since 1932 this type of vitamin D milk has been made commercially available. The product is sometimes referred to as 'metabolized' vitamin D milk. This name is one of convenience only and it is not entirely satisfactory because neither the milk nor the vitamin D has been subjected to any metabolizing process. The vitamin D appears to be imparted unchanged to the milk. The yeast feeding method is used on both 'certified' and ordinary dairy farms.

The expression "certified vitamin D milk" refers to metabolized vitamin D milk of certified grade, produced according to the Methods and Standards of the American Association of Medical Milk Commissions, Incorporated.

Numerous investigators have reported on the clinical effectiveness of metabolized vitamin D milk. Kramer,³ Wyman,⁴ Gerstenberger⁵ and Eliot⁶ and their respective co-workers showed that, if there is any difference, unit for unit, between different types of vitamin D milk, the difference is too small to be of practical significance.

Metabolized vitamin D milk is produced under the joint sponsorship of Standard Brands Incorporated and the Wisconsin Alumni Research Foundation. The irradiated dried yeast intended for use in the feeding of cows may be sold by Standard Brands Incorporated only to dairymen licensed by the Wisconsin Alumni Research Foundation. The approved feeding schedule is made a part of the license agreement and before a license is issued the dairymen must present a statement from his local health department, medical milk commission or other official milk control body to the effect that he is responsible, in good standing and qualified to produce the milk under proper conditions. The vitamin D content of the milk produced, as shown by repeated bio-assays, is not less than 400 units of vitamin D per quart. The Council voted to accept pasteurized metabolized vitamin D milk and to grant the use of the seal of acceptance to licensed dairies that conform to the Rules and Decisions of the Council. The requirements and allowable claims for metabolized vitamin D milk are the same as for other types of vitamin D milk containing 400 U. S. P. units of vitamin D per quart.⁷

MINERAL OIL IN FOODS

It is well known that liquid petrolatum is not absorbed from the gastro-intestinal tract¹ and, while it possesses many of the physical properties of edible oils, it yields no calories. Because of these properties, mineral oil is extensively used in the treatment of constipation and, to a lesser extent, in replacing fat in certain foods, chiefly mayonnaise and salad dressings, and a few other products. These special food preparations are useful in diets in which restriction of calories or of fats is required, as in the selection of foods for reducing weight, but their indiscriminate use is undesirable.

It was reported by Burrows and Farr² and by Dutcher and his collaborators³ in 1927 that mineral oil interferes with the utilization of vitamin A by experimental animals. This observation has been verified and clarified by additional reports which have since appeared in the scientific literature.⁴ Jackson found that the ingestion of mineral oil resulted in a considerable loss of vitamin A to the animal organism if the oil was administered with the source of vitamin A but not if the mineral oil were given at some other time of the day. Later reports brought out the interesting fact that different results could be expected with different sources of vitamin A. Mineral oil has a marked effect on the absorption of carotenes but has little effect on the absorption of vitamin A itself. The carotenes are provitamin A found

in plant tissues and they are hydrocarbons, while vitamin A, which is derived from animal sources, is a complex alcohol Dutcher⁵ has suggested that the hydrocarbons of the unassimilated mineral oil in the intestine possess a greater solvent effect on the carotenes than on vitamin A.

It is apparent that liquid petrolatum would be a poor vehicle for vitamin A and particularly for provitamin A, and its use in this connection could not be countenanced. On the other hand, it appears that in the amounts usually prescribed (15 cc. from one to three times daily for adults) and under the conditions which should be observed (not to be taken at mealtime), the effect of liquid petrolatum on the absorption of vitamin A of the human diet probably is of little consequence. When incorporated in foods, however, so that the mineral oil is taken at mealtime, it is obvious that there is danger of interference with the absorption of the fat soluble vitamins. Further, the indiscriminate use of foods containing mineral oil by persons who have loose bowels might cause further looseness and thus interfere with the utilization of other vitamins and minerals.

The Council therefore advises strongly against any indiscriminate dosage of mineral oil either alone or incorporated in special foods. Those food products containing mineral oil will be considered for acceptance as special items with limited usefulness to be taken under the direction of a physician.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C. BING, Secretary

MEYENBERG EVAPORATED GOAT MILK

Manufacturer—Meyenberg Milk Products Company, Salinas, Calif.

Description—Canned evaporated goat milk.

Manufacture—Fresh goat milk is inspected, weighed, sampled, filtered, standardized to the desired ratio of fat to solids, evaporated in vacuo at 49° C., homogenized at 2,500 pounds pressure, cooled to 10° C., standardized for total solids, and mechanically filled into cans which are sealed and processed according to the procedure usual for evaporated cow's milk. The equipment used during the entire process is made from stainless steel and glass. Milk is produced in accordance with the regulations of the state of California.

Analysis (submitted by manufacturer)—Moisture 75.7%, total solids 24.3%, ash 1.6%, fat (ether extract) 7.2%, protein ($N \times 6.25$) 8.0%, sucrose none, lactose 8.4%.

Calories—1.3 per gram 37 per ounce

WATKINS BRAND FREE RUNNING TABLE SALT, IODIZED

Manufacturer—The Watkins Salt Company, Watkins Glen, N. Y.

Description—Granulated table salt containing magnesium carbonate (1 per cent) as a caking inhibitor and potassium iodide (0.02 per cent).

Manufacture—Brine, obtained by returning water pumped into the salt veins by drilled wells, is treated with milk of lime, preheated and stored to permit the settling of insoluble matter. The solution is filtered and evaporated. The resulting salt is washed in brine, dried and screened for size. Definite amounts of potassium iodide and magnesium carbonate are added and the salt automatically is packed in cartons.

Analysis (submitted by manufacturer)—Moisture 0.1%, total solids 99.9%, sodium chloride ($NaCl$) 98.5%, magnesium carbonate ($MgCO_3$) 1.0%, calcium sulfate ($CaSO_4$) 0.34%, calcium chloride ($CaCl_2$) 0.04%, potassium iodide (KI) 0.02%, iron and aluminum oxides nil, calcium carbonate ($CaCO_3$) nil, magnesium sulfate nil, magnesium chloride nil.

VALORA BRAND LEMON JUICE 100% PURE

Manufacturer—Santa Barbara Citrus Juice Company, Inc., Orange, Calif.

Description—Canned, pasteurized California lemon juice practically equivalent to fresh lemon juice in vitamin C content.

Manufacture—Selected tree-ripened fruit is washed, inspected, automatically cut in halves and reamed by hand. The juice is strained, deaerated, vacuum filled into cans, vacuum sealed, pasteurized and immediately cooled.

Analysis (submitted by manufacturer)—Moisture 90.5%, total solids 9.5%, ash 0.34%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 0.5%, reducing sugars (as invert) 1.9%, sucrose 0.14%, crude fiber 0.03%, carbohydrates other than crude fiber (by difference) 2.6%, titratable acidity as citric acid 5.95%, pH 2.37, vitamin C (titration) 44 mg per 100 cc (900 International units).

Calories—0.1 per gram 3 per ounce

Vitamins—A rich source of vitamin C

SEXTON BRAND FRUIT FOR SALAD, WATER PACKED

Manufacturer—John Sexton & Company, Chicago

Description—Canned apricots, pears, peaches, pineapple and cherries, packed in water.

Manufacture—Apricots fully tree ripened are inspected, washed, graded, cut, pits removed, again sorted and graded for ripeness. Bartlett pears are graded, ripened, peeled, cut, stemmed, cored, inspected, immersed in brine solution and washed. Yellow cling peaches fully tree ripened are mechanically cut, pitted, lye peeled, washed, inspected, graded for size and washed. Fancy sliced pineapple packed in juice and Maraschino cherries without added sugar are purchased. Fruit is assembled, washed and filled into cans in proper proportions which are inspected, filled with water, exhausted, sealed and processed.

Analysis (submitted by manufacturer)—(Analysis of entire contents including liquid) moisture 90.3%, total solids 9.7%, ash 0.22%, fat (ether extract) 1.0%, protein ($N \times 6.25$) 0.4%, crude fiber 0.34%, carbohydrates other than crude fiber (by difference) 7.8%.

Calories—0.41 per gram 12 per ounce

Claims of Manufacturer—For diets in which sweetened fruit is proscribed.

LIBBY'S HAWAIIAN PINEAPPLE

FANCY GRADE (1) SLICES (2) TIDBITS (3) LONG SLICES (4) DELUXE STYLE (5) CRUSHED

Manufacturer—Libby, McNeill & Libby, Honolulu, Hawaii

Description—Canned Hawaiian pineapple, cut in various styles, packed in syrup: (1) Slices cut crosswise of the pineapple, (2) machine cut tidbits, (3) slices cut lengthwise of the pineapple, (4) large, irregular machine cut tidbits, (5) broken slices and fruit from the inside of the shell, crushed.

Manufacture—Mature Hawaiian pineapples are mechanically peeled, cored and trimmed. The cylinders of fruit are hand trimmed, machine cut, graded and filled into cans which are subjected to vacuum pressure, filled with syrup, sealed and processed.

Analysis (submitted by manufacturer)—Moisture 74.1% to 75.2%, total solids 24.8% to 25.9%, ash 0.3% to 0.4%, fat (ether extract) 0.09% to 0.15%, protein ($N \times 6.25$) 1.0%, reducing sugar as invert sugar 9.9% to 13.0%, sucrose 7.7% to 9.6%, crude fiber 0.07% to 0.09%, carbohydrates other than crude fiber (by difference) 23.3% to 24.3%, iron (Fe) 0.56 to 1.06 mg per hundred grams, and copper (Cu) 0.15 to 0.24 mg per hundred grams.

Calories—0.9 per gram 25 per ounce

Vitamins—The results of biologic assay submitted by the manufacturer indicate the following vitamin content: International units per hundred grams: vitamin A 44, vitamin B₁ 12, vitamin C sliced pineapple and tidbits 210 to 245, crushed pineapple 140 to 175, Sherman Bourquin units of vitamin G per hundred grams, 10.

PRINCIPLES AND PROPOSALS OF THE COMMITTEE OF PHYSICIANS

The Board of Trustees has especially authorized publication of the following statement

Following the publication of the report of the American Foundation Studies in Government, a small group of physicians, assembled in New York, developed certain principles and proposals which have since been circulated by a self-appointed Committee of Physicians among the medical profession of the United States, with a view to obtaining signatures in their support. During a period of approximately six months, some 430 medical men have apparently permitted the use of their names. Early in November the self-appointed group of physicians released to the press for Sunday, November 7, a statement of principles and proposals to which the names of the 430 signers were affixed. The newspapers generally heralded this action as a revolt against the American Medical Association, in a great majority of the cases indicating that there was a revolt in behalf of "state medicine." The publication of this manifesto and the attached signatures has been heralded with glee by many of those who have been opposing the American Medical Association in behalf of cooperative practice, sickness insurance, and various fundamental changes in the nature of the practice of medicine. Within the last week another series of proposals has come from another self-appointed group requesting signatures of physicians. This series of proposals includes the suggestion for enabling legislation for sickness insurance.

The American Medical Association is an organization of physicians along strictly democratic lines. Representatives of county medical societies send delegates to state medical societies and these, in turn, send their delegates to the House of Delegates of the American Medical Association. It is possible for any physician, through his delegate, to obtain consideration of any proposal which he may wish to bring to the attention of the House of Delegates. At the Atlantic City session the delegates from New York State presented these principles and proposals, slightly modified, as an action

of the House of Delegates of the Medical Society of the State of New York. They were carried before a reference committee and, in several sessions of that reference committee, considerable numbers of physicians presented arguments for and against their adoption. The House of Delegates, however, after thorough consideration of the report of the reference committee, and with full cognizance of the method of development of these principles and proposals, and of the considerations which were involved in their passage by the House of Delegates of the Medical Society of the State of New York, did not accept them. The House of Delegates did, however, point out the willingness of the medical profession to do its utmost today, as in the past, to provide adequate medical service for all those unable to pay either in whole or in part.

Why, then, any necessity for the circulation of petitions presenting proposals for fundamental changes in the nature of development, distribution and payment for medical service? Is there a well designed plan to impress the executive and legislative branches of our government with the view that the American medical profession is disorganized, distrustful of its leaders, undemocratic in its action and opposed to the best interests of the people? Who may profit from such evidence of disorganization? Is there any evidence that the self-appointed Committee of Physicians and the 430 physicians who have affixed their names to these principles and proposals are any better able to represent the opinion of the American medical profession than the democratically chosen House of Delegates of the American Medical Association—one of the most truly representative bodies existing in any type of organized activity in this country today?

The House of Delegates has given its mandate to the Board of Trustees, to the officers and to the employees of the Association. That mandate opposes the principles and proposals emanating from the Committee of Physicians, and equally the new proposals. If the House of Delegates sees fit to depart from the principles now established, it will be the duty of the Board of Trustees, the officers and the employees of the American Medical Association to promote such new principles as the House of Delegates may establish. Until, however, the regularly chosen representatives of the 106,000 physicians who constitute the membership of the American Medical Association (now the largest membership in its history) determine, after due consideration, that some fundamental change or revolution in the nature of development, distribution and payment for medical service in the United States is necessary, physicians will do well to abide by the principles which the House of Delegates has established. They will at the same time deprecate any attempts inclined to lead the executive and legislative branches of our government, as well as the people of the United States, into the belief that the American medical profession is disorganized.

Members of the medical profession, locally and in the various states, are ready and willing to consider, with other agencies, ways and means of meeting the problems of providing medical service and diagnostic laboratory facilities for all requiring such services and not able to meet the full cost thereof. The American Medical Association has reaffirmed its willingness on receipt of direct request to cooperate with any governmental or other qualified agency and to make available the information, observations and results of investigation, together with any facilities of the Association. Thus far, no call has come from any governmental or other qualified agency, for the cooperation of the American Medical Association in studying the need of all or of any groups of the people for medical service, to determine to what extent any considerable proportion of our public are actually suffering from lack of medical care. The offer still stands as evidence of the willingness of the American Medical Association to aid in finding a solution to any or all of the problems in the field of medical care that now prevail.

PREVENTION AND TREATMENT OF MEASLES

The use of convalescent or adult serum in the prevention of measles has been known so long that recent reports serve largely to corroborate previous investigations. Fleming¹ has recently reported an epidemic of measles in a school of 300 boys, in which treatment by adult serum was employed. The term started on January 15, and on January 17 a boy was admitted to the school sanatorium with measles, by February 14 serum was given to all who were susceptible. In the end, seventy of the eighty-five patients with measles were treated with serum. They fell into three groups: 1. To fifteen patients serum was not given, they included the original case and one boy who was reported to have had measles as a child. The average period of fever for this group was 82 days. Complications included one severe case of bronchopneumonia and two cases of middle ear infection. 2. Twenty patients were given serum during incubation. These had an average fever period of 65 days. There were four cases of middle ear inflammation. 3. Finally there were fifty patients to whom serum was given before infection. In these patients the average fever period was 52 days and there were no complications. Fleming concluded therefore that the adult serum had a definite effect in attenuating the disease and in decreasing the incidence of complications but that there was no evidence in this epidemic of any true temporary immunity resulting from the use of the serum.

Hardgrove and his co-workers² recently reported complete protection for 82 per cent of measles contacts

receiving convalescent serum and for 64 per cent of those receiving less than the recommended amount. The serum also appears to have some therapeutic value. The serum is weakened somewhat after one year but retains enough potency to be of use when given in large amounts. Furthermore, they believed that pooled normal serum can be used for the same purpose as convalescent measles serum if large doses are administered. These studies seem to confirm the general impression that convalescent serum is of value in the attenuation of measles. It seems likely that normal adult serum is not as powerful as convalescent serum in this respect, and if Fleming had been able to use the convalescent serum or larger quantities of the adult serum he might have had complete suppression of the measles rather than attenuation. Dosages, however, still have to be standardized and probably depend on several factors, including the source of the serum.

In recent years the use of placental extract in the prevention and modification of measles has also received considerable attention, owing partially at least to the expense and difficulty of obtaining satisfactory convalescent or even normal serum. Thus McKhann and Chu³ reported a series of observations which indicated that placental protein extracts can be prepared and, when given by intramuscular injections to susceptible patients early in the period of incubation, result either in protection or in attenuation. In a more recent paper McKhann⁴ states that the dosage of placental extract necessary is influenced by several factors, including potency, time of administration, age and size of the patient and degree of exposure. In some instances, intramuscular administration is followed by local or general reactions, but such reactions are severe only relatively rarely. Sensitizations to subsequent injections of placental extract have not been found. The immunity following the placental extract is passive in type and of short duration. Thus observations of fifty-four children reexposed to measles within a few weeks after receiving placental extract indicate that the immunity resulting from the injection is insufficient to protect against reexposure occurring more than two weeks after administration.

Montgomery,⁵ using immune globulin of placental origin, attempted to prevent or modify measles in children who were patients in a cross-infected ward. Suggestive but undiagnosable mild attacks of fever occurred after the original contact, but thirty-three days after the original case a child developed a typical attack of measles, although it had received the immune globulin. These observations would seem to indicate that passive immunity resulting from 10 cc doses of

5 Montgomery Alice K. Immune Globulin (Human) Lederle in the Prevention of Measles. *Glasgow M. J.* 10: 89 (Sept.) 1937.

immune globulin is of fairly short duration. This view is similar to that held by McKhann and others. The possibilities resulting from the apparent certainty that both immune serum and placental extract can produce definite although temporary immunity to measles is significant and encouraging in view of the knowledge that measles is much more serious than is generally recognized. Certainly these facts open new possibilities for the identification of a chemical principle of high immunizing power.

CALCIUM AND BLOOD COAGULATION

The enormous literature on the phenomenon of the clotting of blood attests vigorous investigative activity. William Hewson¹ wrote in 1770 of his observation that coagulation could be influenced by salts of various kinds. During the middle years of the nineteenth century active investigation resulted in the discovery that serum contained an organic substance, which could also be extracted from blood clots, that had the power of initiating the coagulation of blood and of various ordinarily incoagulable body fluids. Alexander Schmidt showed in 1872 that inorganic salts had an essential part in the process of clotting. The view that calcium assumes a peculiar role in blood coagulation appears to have arisen with Hammarsten, who vigorously championed the specific nature of its action. Most workers accept the requirement of calcium as constituting a link in the chain of events ending in the formation of the fibrin clot but at present there is a question regarding the point at which this element exerts its influence.

The essential features of the various modern theories of coagulation include a proteim called prothrombin as a normal constituent of the blood. This is changed to thrombin directly or indirectly by a substance (kinase) contained in tissue fluids and platelets, when calcium is present. The resulting thrombin brings about a change of the fibrinogen, ordinarily present in blood, to fibrin, which is the basis of the clot. The point at which calcium acts is in the change of prothrombin to thrombin. Whether it acts merely as a catalyst or actually becomes part of the thrombin, essential for its action, has been the subject of much controversy. Ferguson² has introduced a new factor into the general conception. Using carefully prepared prothrombin and cephalin (kinase) with calcium chloride, he produced thrombin the activity of which was tested on solutions of purified fibrinogen. To test for the presence of calcium in the thrombin, the latter was subjected to decalcification by oxalate or citrate or by dialysis before it was permitted to act on the fibrinogen. Thrombin can lose calcium to the extent of failure to clot the fibrinogen solution if the decalcification is carried out soon after the formation of the thrombin. If the thrombin is allowed to "age" for several hours

before decalcification is attempted, the loss of the calcium no longer prevents clotting. Thus there seems to be a "calcium-containing intermediate complex" which changes to stable thrombin.

An important deduction of the foregoing observations is that the action of the decalcifying anticoagulants is rather more complex than ordinarily conceived; they may prevent clotting by actually precipitating ionized calcium before thrombin has been formed or they may compete with thrombin for the calcium and, if the thrombin-calcium complex is newly formed, will interfere with coagulation by withdrawing the calcium from the complex. These studies have added new details to a commonplace but highly intricate and important vital phenomenon, from such effort with experimental models may come significant improvements in the technic of transfusion.

Current Comment

THE FOURTH OF JULY RECORD

On page 1806 of this issue of THE JOURNAL appears a brief summary of 1937 Fourth of July fireworks injuries. This continues after a lapse of twenty-one years, those summaries which the American Medical Association published from 1903 to 1916 inclusive. Their renewal is necessitated by the unfortunate increase that has since occurred. Fireworks are again a serious menace to life and health. Their control must originate in the respective state legislatures, to be adequate, laws must be enacted by contiguous states. This matter should receive the immediate attention of lawmakers in the attempt to avoid or minimize totally unnecessary deaths and injuries on Independence Day, 1938.

RABIES IN ALABAMA

In Alabama, according to a recent report,¹ it has been impossible to institute or enforce effective measures for controlling rabies in dogs. As a result, the manufacture and distribution of antirabies vaccine has become an expensive and tedious problem of public health administration. From January 1922 to August 1936, 9,282 animals received a positive laboratory diagnosis of rabies. During this period 34,864 individuals were given the antirabies vaccine and forty-two persons died of the disease. There has been a six-fold increase in the incidence of the disease among animals during this period, the fact that human mortality has been maintained at a low rate is apparently due only to the increase in administration of vaccine. Of the forty-two persons who died from rabies, twenty-one had received antirabies vaccine and twenty-one had not. Among the twenty-one persons receiving vaccine who died, treatment for twenty began within six days after exposure and in one after three weeks. The short incubation period of from two to four weeks in thirteen treated

and nine untreated cases indicates that the degree of infection was such that vaccine could hardly have been expected to save many of these patients. Among the treated, 9,800 received Pasteur treatment with a mortality of 0.11 per cent. Since 1930, 25,064 received Semple treatments with ten deaths, or a mortality of 0.04 per cent. These returns, it was pointed out, compare favorably with the larger series reported by McKendrick² in his League of Nations Analytical Reviews.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Meeting of Urologists—The annual meeting of the South-eastern Branch Society of the American Urological Association was held at Birmingham, November 5-6. The following program was presented:

- Drs. Henry W. E. Walther and Robert M. Willoughby, New Orleans: Hormonal Treatment of Benign Prostatic Hypertrophy.
- Dr. Gershom J. Thompson, Rochester, Minn.: Clinical Data Concerning Prostatic Resection.
- Dr. Edwin P. Alyea, Durham, N. C.: Cystoscopic Removal of Large Ureteral Calculi by Modification of the Usual Manipulative Methods.
- Dr. John A. C. Colston, Baltimore: Sulfanilamide (Prontylin) in the Treatment of Genito-Urinary Infections.
- Dr. Nels F. Ockerblad, Kansas City, Mo.: Surgery of the Human Ureter.
- Dr. Clyde Leroy Deming, New Haven, Conn.: Future of Unilateral Nephrectomized Patients.
- Dr. Owsley Grant, Louisville, Ky.: Obstruction at the Vesical Neck in Children.
- Dr. James J. Ravel, Charleston, S. C.: Extravasation from the Lower Urinary Tract.

CALIFORNIA

Plague Infection—According to *Public Health Reports*, October 29, plague infection has been demonstrated in pools of fleas and in pooled tissue and organs taken from rodents in California as follows: In Fresno County, a pool of 111 fleas from twenty-seven fisher's squirrels, eighty-four fleas from 151 golden mantled squirrels, forty-eight fleas from 139 chipmunks and twenty-seven fleas from ten chuckaree (red) squirrels, received at the state department of health laboratory on September 21; a pool of forty-eight fleas from 139 chipmunks and eleven fleas from seventeen chipmunks collected on September 20; a pool of organs from three beechey's squirrels shot on September 14, and a pool of organs from nine golden mantled squirrels collected October 2. In Placer County, plague infection was demonstrated in pooled tissue from seven beechey's squirrels, five chipmunks, two wood rats, two alexandrinus rats and three golden mantled squirrels received at the laboratory October 1.

COLORADO

Annual Hospital Meeting—The Colorado Hospital Association held its thirteenth annual meeting at the Cosmopolitan Hotel, Denver, November 9-10. The speakers included Drs. Paul J. Connor and Roy L. Cleere, president and secretary, respectively, Colorado State Board of Health, Denver, on 'The Future of the Hospital and the Doctor' and 'Future Relations Between Hospitals and the Public Health Agencies'; Robert E. Neff, Iowa City, president, American Hospital Association, 'Patients and Patience'; and Dr. William B. Draper, Denver, 'Facts and Fallacies of Oxygen Administration'.

Midwinter Clinics—The annual midwinter graduate clinics of the Colorado State Medical Society will be held in Denver December 15-17 at the Shirley-Savoy Hotel with the Medical Society of the City and County of Denver acting as host. Guest speakers will include:

- Dr. Herman L. Kretschmer, clinical professor of genito-urinary surgery, Rush Medical College, Chicago.
- Dr. A. Craeme Mitchell, B. K. Rachford, professor of pediatrics, University of Cincinnati College of Medicine.

² McKendrick, A. G. First to Sixth Analytical Review of Reports from 14 tour institutes on the results of Antirabies Treatment. *Quart. Bull. Health Organ. League of Nations*, Geneva, August 1930 to December 1935.

Dr. Robert D. Schrock, professor of orthopedic surgery, University of Nebraska College of Medicine, Omaha.
Dr. Albert J. Brown, professor of surgery at the University of Nebraska College of Medicine, Omaha.
Dr. Don C. Sutton, associate professor of medicine, Northwestern University Medical School, Chicago.

Clinics will be conducted in the mornings at the Colorado General, Children's General and Denver General hospitals.

CONNECTICUT

Laboratory Pneumonia Service Extended—On October 1, the bureau of laboratories of the state health department began typing for types I, II, IV, V, VI, VII, VIII and XIV. When the retrenchment program for the bureau was put into effect, pneumonia typing was restricted to types for which therapeutic antisera were available. Since then antisera for three additional types have been marketed and the laboratories have extended the typing service to include them. Should other therapeutic antisera become available to physicians, the laboratories will attempt to test for the specific types involved, the *Connecticut Health Bulletin* announces.

Public Health Day—The Connecticut Public Health Association has designated the day of its winter meeting, December 1, in Hartford, as "public health day." A conference for health officers, planned by the state department of health, has been arranged for a morning session. Features of the afternoon program will include a discussion of the state cancer control program by Dr. Charles L. Larkin, Waterbury, and a symposium on the treatment and control of pneumonia with the following speakers: Dr. John A. Wentworth, Hartford, Irma E. Reeve, R.N., New Haven, Dr. Mario L. Palmieri, Middletown, Dr. Millard Knowlton, Hartford, and Friend Lee Mickle, D.Sc., Hartford.

DISTRICT OF COLUMBIA

Society News—Dr. Arthur M. Shipley, professor of surgery, University of Maryland School of Medicine, Baltimore, addressed the Washington Academy of Surgery, October 8, on 'Surgery of the Biliary Duct Apparatus.' The academy will be addressed December 10 by Dr. Isaac A. Bigger, Richmond, Va., on 'Surgery of the Heart and Pericardium.'

Symposium on Sulfanilamide—The Academy of Medicine of Washington devoted its fall meeting November 17 to a symposium on sulfanilamide. Dr. Eli K. Marshall, Jr., Baltimore, discussed 'Certain Phases of the Pharmacology of Sulfanilamide'; Dr. Sanford M. Rosenthal of the National Institute of Health, 'Sulfanilamide and Related New Compounds in Experimental Infections'; and Dr. Frederick A. Reuter, clinical professor of urology, George Washington University School of Medicine, 'New Work with Sulfanilamide in Clinical Urology.'

ILLINOIS

Retires as Director of Laboratories—Howard J. Shaugnessy, Ph.D., has resigned as director of the division of laboratories of the Illinois State Department of Health, Springfield, to become associate professor of bacteriology and public health at the University of Colorado School of Medicine, Denver. Dr. Shaugnessy has held the position with the Illinois department since 1931.

Society News—Dr. Frederick B. Moorehead, Chicago, discussed 'The Use of Plastic Traction in Jaw Fractures' before a joint meeting of the Sangamon County Medical Society and the G. V. Black District Dental Society in Springfield, November 4.—Dr. Philip Thorek, Chicago, discussed 'The Direct and Differential Diagnosis of Acute Gallbladder Disease' before the De Witt County Medical Society at Clinton, October 20.—Drs. Ralph M. Tyson and Chevalier L. Jackson, Philadelphia, discussed 'Diagnosis and Treatment of Foreign Bodies in the Respiratory Tract' before the Peoria City Medical Society in Peoria, November 16. At a meeting of the society, November 2, Drs. Harry Costeff and Julius Steinfeld, Peoria, discussed 'Insulin Shock and Other Methods of Therapy in Schizophrenia'.—Dr. Paul H. Harmon, Springfield, discussed 'Anterior Poliomyelitis' before the Madison County Medical Society, November 5.

Chicago

University News—Loyola University School of Medicine has annexed the dispensary and outpatient clinical facilities of Mercy Hospital, 2536 Calumet Avenue, to supplement the overcrowded clinics at the medical school. Dr. John G. Powers has recently been officially appointed assistant dean of the medical school.

Society News—At a joint meeting of the Chicago Orthopaedic Society and the Chicago Roentgen Society, November 12, the speakers were Drs Daniel H Levinthal and Hollis E Potter on "Benign Tumors of Bone—Diagnosis and Treatment" and "Roentgenological Aspects of Low Back Pain" respectively—Dr Charles B Huggins, among others, addressed the Chicago Urological Society November 18 on "Treatment of Tuberculous Wounds Following Nephrectomy"

Book Fair for Benefit of Medical School—The Women's Faculty Club of Northwestern University Medical School is sponsoring a book fair, December 2-4, and a book ball Saturday evening, December 4, for the benefit of the medical school clinics. The book fair will be held on the Chicago campus of the university and the ball in the Knickerbocker Hotel. The fair will consist of a display of rare books, prints, fine bindings, valuable first editions, original manuscripts of famous authors, new and used volumes, periodicals, magazines, lithographs, water-color paintings, Christmas cards, gifts and novelties. There will be an author's tea Friday afternoon and lectures Thursday including one by Mrs Arthur Byfield on "Adventuring Down the Menu." Saturday there will be a "children's day celebration" in Thorne Hall. Costumes will be optional at the ball, although it is suggested that those attending appear as characters from the printed page. Additional information may be obtained from Mrs Gerard Krost, 6900 Paxton Avenue, Chicago, telephone Hyde Park 2882.

INDIANA

Society News—Arrangements have been completed to hold all business and dinner meetings of the Indianapolis Medical Society on the third floor of the Indianapolis Athletic Club each Tuesday evening in the future—The Northeastern Indiana Academy of Medicine was addressed at Kendallville, October 28, by Drs Arthur E Mahle, Chicago, on "Recent Advances in Medical Management of Peptic Ulcer"

Gifts to Medical School Library—Dr William N Wishard Sr, for many years professor of genito-urinary surgery, Indiana University School of Medicine, Indianapolis, has given a collection of pictures to the library of the university's medical center. The collection includes a photograph of the nine men who composed the last faculty of the medical college that was organized in Indianapolis in 1869 and which was combined with the College of Physicians and Surgeons in 1878 to form the Medical College of Indiana, and other photographs of interest in the development of the medical school. About seventy-five medical books were also given to the library by Drs George C Fisher and Edwin S Knox, both of Indianapolis.

LOUISIANA

Society News—The Tri-Parish Medical Society was addressed at Tallulah October 5 by Drs Harold G F Edwards and Edgar L Sanderson, both of Shreveport, on "Cancer Is Curable" and "Treatment of Indigent Patients in the Future," respectively—Dr Tom Spec Jones, Baton Rouge discussed "Typhus Fever" before the Bi-Parish Medical Society October 6—A symposium on syphilis was presented before the Orleans Parish Medical Society, New Orleans, November 8 by Drs John G Menville, Edgar Hull, James K Knowles, John R Schenken and John A Trautman.

MARYLAND

Personal—Dr Paul Cohen has been named superintendent of the Eastern Shore Branch, Maryland Tuberculosis Sanatorium, Salisbury, succeeding the late Dr Charles D Steenken—Dr Harry Friedenwald, Baltimore, has been made an honorary fellow of the Jewish Academy of Arts and Sciences.

Society News—The Baltimore City Medical Society held a joint meeting with the Medical Society of the District of Columbia in Baltimore, November 19. The speakers were Drs Charles R L Halley, Washington, D C, on "Typhoid Types of Fever, Frequency and Problems of Diagnosis," Edgar W Davis, Washington, D C, "Endobronchial Tumors: Diagnosis and Treatment," and Arthur C Christie, Washington, D C, "Recent Advances and Trends in Radiology." The Baltimore society was addressed November 5, among others, by Drs Harvey G Beck and George M Suter on "The Role of Carbon Monoxide in the Etiology of Myocardial Disease."

Syphilis Control Activities—With the election of Dr Harry M Robinson, Baltimore, as permanent chairman, October 21, formal activities of the state's syphilis control program were instituted. Two statewide committees to carry on the program were approved, according to the Baltimore Sun. The committee on legislation will be headed by State Senator Raymond E Kennedy, and the committee on medical facilities

will be headed by Dr Joseph Earle Moore, director of the syphilis clinic of Johns Hopkins Hospital. Seven subcommittees will work under Dr Moore, covering epidemiology, dispensaries, libraries, hospitalization, neurosyphilis, syphilis in Negroes, and prenatal and congenital syphilis, while five subsidiary committees will be named to represent sections of the state. A survey to determine the extent of and facilities for the treatment of syphilis will be made. The deadline for the study will be February 1, when the material gathered will be incorporated into a report for the governor for legislative action.

MASSACHUSETTS

Society of Physical Therapy Changes Name—At a recent meeting in Boston the New England Physical Therapy Society changed its name to the New England Society of Physical Medicine. Dr Robert T Phillips, Boston, addressed the meeting, November 17, on "Practical Physical Medicine for Chronic Arthritis."

Personal—Dr George D Dalton, Quincy, has been appointed medical examiner of Norfolk County, succeeding the late Dr Frederick E Jones, who held the post for almost forty years—Dr Rowland Godfrey Freeman Jr, New York, has been appointed assistant psychiatrist of the Judge Baker Guidance Center, Boston.

MICHIGAN

Interns' Case History Contest—The East Side Physicians' Association agreed at a meeting October 21 to sponsor a contest for the best case history written this year by a first year intern of an East Side Detroit hospital, according to *Detroit Medical News*. Prizes of \$100, \$50 and \$25 respectively will be offered for the best three papers submitted.

Society News—At a meeting of the East Side Physicians' Association, Detroit, November 18, the speakers were Drs Robert B Kennedy and Robert L Schaefer on "Causes and Treatment of Sterility" and "Clinical Indications for Anterior Pituitary-like Sex Hormones" respectively—The Washtenaw County Medical Society was addressed November 9 by Drs Arthur C Curtis, on sulfanilamide, Russell W DeJong, benzedrine, and Jerome W Conn, protamine zinc insulin. All are of Ann Arbor—Dr Maurice B Visscher, Minneapolis, addressed the medical section of the Wayne County Medical Society, Detroit, November 8, on "Physiological Principles of Importance in Heart Failure and Its Treatment." Dr Andrew C Ivy, Chicago, discussed jaundice before the society, November 15—Dr Ward F Secley, Detroit, discussed "Heart Disease in Pregnancy" before the Calhoun County Medical Society, Battle Creek, November 2—Dr Joseph L Baer, Chicago, addressed the Detroit Gynecological Society, November 2, on "The Cervix in Obstetrics and Gynecology."

Director of New Hospital Commission Appointed—Dr Joseph E Barrett, Taunton, Mass., has been appointed director of the State Hospital Commission of Michigan, created by the last legislature under a law effective October 29, to supervise and control all state mental hospitals. Dr Theophile Raphael, Ann Arbor, has been appointed to the commission, the only physician member at the time of the report. Dr Leo G Christian, Lansing, chairman of the legislative committee Michigan State Medical Society, was also appointed but resigned before the commission held its first meeting November 10. Dr Barrett graduated at the University of Tennessee School of Medicine in 1922 and served at the State Hospital for Nervous Diseases, Little Rock, Ark., from 1923 to 1928 when he was appointed assistant superintendent of the Taunton State Hospital. In 1931 he was made assistant to the commissioner in the Massachusetts Department of Mental Diseases and in 1934 assistant commissioner. Since resigning from the Massachusetts department in June 1937 he has made surveys of state hospitals in Iowa and Virginia for the National Committee for Mental Hygiene.

MINNESOTA

Personal—Dr Edward J Engberg, St Paul, has been appointed superintendent of the Minnesota School for Feeble-minded, Faribault, to succeed Dr James Moorhead Murdock, retired—Dr Gilbert G Cottam, Minneapolis, editor of the *Bulletin* of the Hennepin County Medical Society, has been appointed assistant editor of *Minnesota Medicine*, succeeding Dr Chauncey A McKinlay, resigned.

Society News—Dr Thomas A Peppard, Minneapolis, discussed "Symptomatology of the Various Leukemic States," and Dr Owen H Wangenstein, Minneapolis, "Importance of Immobilization and Posture in the Treatment of Acute Infections of the Extremities" before the Minnesota Academy of

Medicine, November 10—Dr Tinsley R Harrison, Nashville, Tenn, discussed 'Cardiac Dyspnea' before the Minnesota Pathological Society, November 16—Dr Carl V Weller, Ann Arbor, Mich, addressed the Hennepin County Medical Society, Minneapolis, November 10, on 'Intrinsic Factors in the Causation of Cancer'

Dr Meyerding Honored—Dr Edward A Meyerding, St Paul, executive secretary of the Minnesota Public Health Association and secretary of the Minnesota State Medical Association, was honored at a testimonial dinner, November 11 in recognition of his many years' service in the field of public health Dr Sidney A Slater, superintendent, Southwestern Minnesota Sanatorium, Worthington, acted as toastmaster, and speakers included Drs Jay Arthur Myers, Minneapolis president of the National Tuberculosis Association, Alfred W Adson, Rochester, president of the state medical association Olaf J Hagen, Moorhead, president of the Minnesota Public Health Association for the past year, James M Hayes, Minneapolis, president-elect of the state medical association, Everett K Geer, St Paul, Arthur T Laird, Nopeming, and Mrs A L Sperry, Owatonna who represented the volunteer Christmas Seal workers of the state Dr Meyerding has served as executive secretary of the public health association for fourteen years Prior to that he was director of the division of hygiene and special classes of the public schools of St Paul for fifteen years He spent two years in the U S Army Medical Corps during the World War and is now a colonel in the reserve He has been secretary of the state medical association since December 1924 but is now on leave of absence from active duty

NEBRASKA

Society News—Drs Howard B Hamilton and Benjamin Carl Russum, Omaha, addressed the Omaha-Douglas County Medical Society, November 9, on 'Appendicitis in Childhood' and 'Fatal Pulmonary Embolism' respectively Drs William R Hamsa and Frank Lowell Dunn addressed the society, October 12, on 'Evaluation of Scoliosis Treatment' and 'Treatment of Arthritis' respectively—Dr Robert D Schrock, Omaha, addressed the Platte-Loup Medical Society, October 13, on 'Plaster versus Splints in Fracture of the Long Bones'

NEW JERSEY

Society News—Dr Frank H Lahey, Boston addressed the Bergen County Medical Society, Hackensack, November 9, on 'Thyroid Diseases,' and Dr Edward M Z Hawkes, Newark, first vice president of the Medical Society of New Jersey, discussed activities of the state society

Tuberculosis Meeting—Dr Jay Arthur Myers Minneapolis, president of the National Tuberculosis Association was the guest speaker at the annual meeting of the New Jersey Tuberculosis League in New Brunswick, October 22 Among other speakers were Drs Henry H Kessler, Newark Harold S Hatch, Morristown Joseph R Morrow, Ridgewood, and Joseph H Kler, New Brunswick

NEW YORK

Pilgrim Hospital Head Appointed—Dr Harry J Worthing medical superintendent of the Willard State Hospital has been appointed medical superintendent of Pilgrim State Hospital, Brentwood, to succeed Dr William J Tiffany, who recently became state commissioner for mental hygiene Dr Worthing graduated from Syracuse University College of Medicine, Syracuse, in 1913

Society News—Dr Stanley P Jones Mattituck addressed the Suffolk County Medical Society in Riverhead October 28 on undulant fever—Dr Edgar A Vanderveer, Albany, was elected president of the New York State Society of Industrial Medicine at its annual meeting in Corning November 4—Dr William W Woodruff, Saranac Lake, addressed the Jefferson County Medical Society, Watertown, in October on 'Surgery of the Chest'—Drs Alvan L Barach and Norman H Plummer New York and Edward S Rogers, Albany presented a program on pneumonia before the Warren County Medical Society, Glens Falls, October 13—Thomas J Cook, DDS Philadelphia, addressed the Dutchess County Medical Society, Poughkeepsie, November 10 on 'Diseases of the Mouth of Interest to the Physician and Dentist in Relation to Systemic Disease'

Cancer Exhibit and Program—The Medical Society of the County of Nassau and the Nassau County Cancer Committee jointly presented a public exhibit and program on cancer October 19 which was attended by about 500 persons in spite of inclement weather Dr Louis C Kress Buffalo addressed

an audience of women in the afternoon on 'Cancer—A Challenge to Women' In the evening Dr Kress addressed a regular meeting of the medical society on 'The Responsibility of the Family Physician to the Cancer Patient,' and Dr Stanley P Reimann, Philadelphia, on 'The Effects of Hormones upon Malignancy' The exhibit included material on cutaneous granulomas, inflammatory carcinoma of the breast, cancer of the lip, pathogenesis of skin cancer, Wilms' tumor of the kidney, development of cancer in burn scars, cancer of the kidney and of the urinary tract, bone tumors, cancer of the lung, melanoma, cancer of the rectum and educational matter prepared by various cancer organizations

New York City

Personal—Dr George Gray Ward, emeritus professor of gynecology of the New York Post-Graduate Medical School and Hospital, Columbia University, was made an honorary fellow of the British College of Obstetricians and Gynecology October 27

Hospital Presents Clinical Seminar—The Beth-El Hospital, Brooklyn presented its fourth annual clinical seminar October 4-7 Mornings were devoted to rounds at the hospital, afternoons and evenings to sessions at the Silver Manor Among speakers at the evening meetings were Drs Andrew C Ivy, Chicago, on 'Physiology of the Gastro-Intestinal Tract', Frederick Tilney, New York, 'Encephalitis,' and John E Jennings, Brooklyn, 'Cancer of the Breast—Diagnosis, Radiation, Surgery'

Society News—The annual dinner of the Association for the Advancement of Industrial Medicine and Surgery was held October 20 with the following speakers Dr Albert E Russell, U S Public Health Service, 'Syphilis Control in Industry', Dr Byron P Stookey, 'Herniations of Nucleus Pulposus in Relation to Low Back Pain,' and Mr Bernard Botem, special prosecutor in accident fraud cases 'Present Medicolegal Trends'—The Philadelphia Orthopedic Club met with the section of orthopedic surgery of the New York Academy of Medicine November 19 Among the speakers were Drs Arthur Krida on 'An Encircling Fascial Band Operation for Hallux Valgus and Splay Foot', Albert B Ferguson, 'A Standard of Anteroposterior Alinement of the Lumbosacral Joint, with Deductions Concerning Development and Displacement,' and Charlton Wallace, 'Summary of Results of the 1935 Epidemic of Polymyositis'—Drs Robert H Melchionna and James R Lisa addressed the New York Pathological Society, November 18, on 'A Study of the Pharyngeal Pituitary Gland' and 'Pathological Changes of the Heart in Sudden Death' respectively

NORTH CAROLINA

Meeting of Urologists—Dr Homer G Hamer, Indianapolis, was the guest speaker at the twelfth annual meeting of the North Carolina Urological Association in Asheville, October 17-18 on 'Diagnosis and Treatment of Metastatic Infections of the Kidney' Dr Claude B Squires, Charlotte, was elected president

District Meetings—A symposium on infections as related to general practice was presented at a meeting of the Eighth District Medical Society in Winston Salem, October 19, by the following speakers Drs Oliver J Hart and William H Sprunt Jr, Winston-Salem, Kenneth B Geddis High Point William S Hester, Reidsville, and Moir S Martin, Mount Airy The guest speaker was Dr Sylvia Allen, Baltimore, on 'The Effect of Infections on Mental and Emotional Diseases'—The fall meeting of the Tenth District Medical Society was held at Hendersonville November 3 Drs Donnell B Cobb, Goldsboro and Wingate M Johnson, Winston-Salem, president of the Medical Society of the State of North Carolina were the guest speakers Dr Cobb spoke on 'Congenital Pyloric Stenosis'

OHIO

Society News—Drs Frank E Stevenson and Merlino L Cooper Cincinnati addressed the fall meeting of the eighth district of the Ohio State Medical Association, October 15, in Zanesville on 'Clinical Aspects of Infantile Paralysis' and 'Etiology and Bacteriology of Infantile Paralysis' respectively—At a meeting of the ninth district in Portsmouth, October 14, the speakers were Drs Fred W Rankin, Lexington, Ky, on 'Modern Management of Cancer in the Gastro Intestinal Tract', Clifford J Strahlev, Cincinnati, 'Cardiac Symptoms and Treatment' and George M Lyon Huntington W Va, 'The More Common Infections of Children and Their Management'

Graduate Program in Akron—The Summit County Medical Society presented its sixth annual graduate program at the Mayflower Hotel, Akron, November 10. The speakers were Drs B B Vincent Lyon, Philadelphia, who spoke on "Methods of Diagnosis and Treatment of Cholecystitis" and "Diagnosis and Management of Peptic Ulcer", Max Cutler, Chicago, "Breast Tumors" and "Recent Developments in Radiation Treatment of Cancer", Stewart H Clifford, Boston, "Intracranial Hemorrhage in the New-Born" and "Diagnosis and Treatment of Important Diseases of the New-Born". Mr A R Jaqua, Cincinnati, gave an address at the dinner on "Economic Pitfalls for the Doctor and His Estate".

Scholarship Offered by State University—The Elizabeth Clay Howald Scholarship of \$3,000 is offered by Ohio State University, Columbus, to "any person who has shown marked ability in some field of study and has in progress work the results of which promise to constitute important additions to our knowledge". The recipient will be expected to devote full time to his investigations, which may be carried on at any place where there are particular advantages for his field of study if he has at any time been connected with the university as student or staff member. If he has not had any connection with the university, he must carry on his work there. Applications must be filed with the dean of the graduate school not later than March 1, 1933. The appointment will be made April 1 and the term will begin July 1, to extend to July 1, 1939.

PENNSYLVANIA

Annual Postgraduate Day—The Allegheny Valley Hospital, Tarentum, offered its annual postgraduate day November 9 with a group of speakers from Johns Hopkins University School of Medicine, Baltimore as follows: Drs Benjamin M Baker Jr, on "Circulatory Failure" and "The Hypertensions", William F Rienhoff Jr, "Surgical Treatment of Pulmonary Diseases" and "Stomach Surgery," and John A C Colston "Kidney Conditions" and "Sulfanilamide in Treatment of Genito-Urinary Diseases".

Twenty-Fifth Anniversary of State Hospital—The twenty-fifth anniversary of the opening of the Allentown State Hospital was celebrated October 12 with a special program. An oil painting of Dr Henry I Klopp, who has been superintendent of the hospital since it was founded, was unveiled as the gift of the medical societies of Lehigh, Northampton and Bucks counties and the Lehigh Valley Homeopathic Society. Dr William C Sandy, Harrisburg, secretary of the American Psychiatric Association, paid tribute to Dr Klopp. Speakers on the program were Drs Sandy, on "Progress in the Hospital Care of the Mentally Ill During Twenty-Five Years", Earl D Bond, Philadelphia, "Evolution of Mental Hygiene in Twenty-Five Years," and James Allen Jackson, Danville, "Extra-Institutional Clinical Activities in Twenty-Five Years".

Philadelphia

Temple University Appointments—Dr William N Parkinson, dean of Temple University School of Medicine, has been appointed vice president of the university. Dr Oliver S English was recently promoted to be professor of psychiatry.

Personal—Charles Kurtzhals, Chester, formerly executive secretary of the Delaware County Tuberculosis Association, has been appointed executive director of the Philadelphia Health Council and Tuberculosis Committee, to succeed the late Mr Harvey Dee Brown.

Society News—The Philadelphia County Medical Society observed Pennsylvania State Health Day with a program November 10, with the following speakers: Drs William C Hunsicker, city director of public health, on "Philadelphia Water", Walter S Cornell, director of medical inspection, board of education, "Health Status of Philadelphia School Children", Robert L Gilman, "Control of Syphilis," and Hobart A Reimann, "Proposed Work of a Pneumonia Commission". Speakers at a meeting of the Philadelphia Pediatric Society, November 9, were Drs Francis F Schwenker, Baltimore, on "Chemotherapy of Acute Infections of the Nervous System", John A Kolmer, "Vaccination Against Experimental Meningococcus Meningitis," and Donald M Pillsbury, "Acetarsone in Therapy of Prenatal Syphilis". Dr Ralph S Muckenfuss, New York delivered the annual Gross Lecture of the Pathological Society of Philadelphia November 11 on "Epidemic Encephalitis". Speakers before the Philadelphia Psychiatric Society, November 12 were Drs Robert S Bookhammer and Earl I Saxe on "Preliminary Report on Metrazol Therapy of the Psychoses" and Harold D Palmer and Stephen H Sherman, "A Study of Involutional Melancholia".

Pittsburgh

Society News—At a meeting of the Allegheny County Medical Society November 16 the speakers were Drs Thomas T Sheppard on "Diagnosis and Treatment of Acute Respiratory Infections", George V Foster, "The Use of Fascia Lata in the Repair of Hernia", Stuart N Rowe, "Bilateral Parasagittal Brain Tumors," and Mr Elbert R Moses of the Pittsburgh School of Speech, "Fundamentals of Good Speech."

RHODE ISLAND

New England Surgical Meeting—The annual meeting of the New England Surgical Society was held in Providence October 1-2. Demonstrations were arranged at the Rhode Island and Memorial Hospitals and scientific programs were presented at the Rhode Island Hospital and the Rhode Island Medical Library Auditorium. Among those who presented papers were:

Dr Philemon E Truesdale Fall River, Mass Subperiosteal Resection of the Manubrium for Funnel Chest

Dr George R Dunlop Worcester, Mass Acute Hemorrhagic Pancreatitis

Dr Charles C Lund Boston Operative Treatment of Ulcerative Colitis

Dr John S Hodgson Boston Relief of Pain in Malignant Disease

Dr Horace K Sowles Boston, Reconstruction Operations for Hypertrophy of the Female Breast

Dr John M Birnie, Springfield, Mass, was elected president

and Dr John F Gile, Hanover, N H, secretary

TEXAS

Society News—Dr Bernard H Bayer, Houston, addressed the Harris County Medical Society, Houston, October 13 on "Perforated Peptic Ulcer". Dr Foster Kennedy, New York was the guest speaker at the semiannual meeting of the Texas Surgical Society in San Antonio October 11-12, his address was on "The Organic Background of Mind". Dr Herman W Johnson, Houston, addressed the Jefferson County Medical Society, Beaumont, October 11, on "Management of Obstetrical Emergencies". The annual meeting of the Panhandle Medical Society was held in Pampa October 12-13, with the following guest speakers, among others: Drs Arthur E Hertzler, Halstead, Kan, on "Operating Room Diagnosis of Uterine Bleeding", Morris Edward Davis, Chicago, "Treatment of Hemorrhage Late in Pregnancy", Otto Jason Dixon, Kansas City, Mo, "Modern Treatment of Mastoid Disease" and James R Jaeger, Denver, "Surgery of the Cranial Nerves".

VERMONT

Typhoid at Brandon—Eight cases of typhoid with one death occurred in a single family in Brandon recently, according to a newspaper report. The first patient was an 8 year old girl who became ill after swimming in a river. Subsequently seven other members of her family developed typhoid. A brother died October 14.

VIRGINIA

Personal—Dr Warren A Colton, clinical director of the Veterans' Administration Facility, Kecoughtan, has been named chief medical officer to succeed Dr Edward N Schilling, who was recently transferred to Atlanta. Dr Harvey C Hardegree, recently on the staff at Excelsior Springs, Mo has succeeded Dr Colton as clinical director.

Specialty Society Elections—Several specialty societies held their annual meetings and elected officers during the recent meeting of the Medical Society of Virginia in Roanoke. Dr Frederick M Hodges, Richmond, was made president of the Virginia Roentgen Ray Society, and Dr Vincent W Archer, Charlottesville, secretary. Dr Foy Vann, Norfolk was elected president and Dr Bernard H Kyle, Lynchburg secretary of the Virginia Orthopedic Society. Dr W Ambrose McGee, Richmond, was made president and Dr John V Bishop, Roanoke, secretary of the Virginia Pediatric Society. The Virginia Society of Obstetricians and Gynecologists elected Dr Flavius O Plunkett, Lynchburg, president, and Dr Eugene S Groseclose, Lynchburg, secretary. Dr William W S Butler, Roanoke, was elected president of the Virginia Urological Society and Dr Lawrence T Price, Richmond secretary.

WEST VIRGINIA

Schwinn Lecture—Dr Arthur L Jones Wheeling delivered the second Jacob Schwinn Lecture of the Ohio County Medical Society in Wheeling November 19 on "Obstructive Uropathy". The lecture was established in honor of Dr Uropathy. The lecture was established in honor of Dr Schwinn, who has practiced more than fifty years in Wheeling and has served as president of the county society and of the West Virginia State Medical Association. He is 82 years old.

WISCONSIN

Physicians Honored—Citizens of Little Chute gave a testimonial dinner October 13 to honor Dr. Joseph H. Doyle on his fortieth year of medical practice. Dr. Doyle graduated from the Wisconsin College of Physicians and Surgeons, Milwaukee, in 1897. He has been president of the village school board for twenty-one years and a director of the bank since its organization in 1907. In 1910 he was president of the Outagamie County Medical Society. The Sauk County Medical Society honored Dr. Marcus Bossard, Spring Green, with a special program October 28 marking his fiftieth year of practice. Dr. Bossard graduated from Bellevue Hospital Medical College, New York, in 1886 and after a year of graduate work began practice in Spring Green in 1887. He has also practiced in Milwaukee and Prairie du Sac. Guest speakers at the dinner were Drs. Harold E. Marsh, Reginald H. Jackson and Addie M. Schwittay, all of Madison.

Committee to Study Hospital Insurance—At the recent annual meeting of the Medical Society of Wisconsin a special committee was appointed to make a thorough study of hospital insurance, reviewing the entire field of hospital management in Wisconsin with a view to the possible need for an insurance program. Special actuarial and legal counsel will be employed to study the element of risk and thus develop a sound factual basis for the work of the committee. Members of the committee are Drs. Stanley J. Seeger, Milwaukee, chairman, Stephen E. Gavin, Fond du Lac, Raymond G. Arveson, Fred-eric, Edward L. Tharinger, Milwaukee, Albion H. Heidner, West Bend, Mr. J. George Crownhart, Madison, secretary of the state medical society, Sister Mary Bernadette, superintendent of St. Mary's Hospital, Madison, Rev. H. L. Fritschel, Milwaukee, administrator of Milwaukee Hospital, Mrs. C. D. Partridge, Cudahy, executive secretary of the Wisconsin State Nurses' Association, and Mr. C. I. Wollan, La Crosse, manager of La Crosse Lutheran Hospital.

GENERAL

Special Board Examination—The American Board of Dermatology and Syphilology announces that a written examination for Group B applicants will be held in various cities April 16. Oral examinations for applicants in groups A and B will be given in San Francisco, June 13-14, 1938. Applications should reach the secretary, Dr. Clarence Guy Lane, Boston, before Feb. 15, 1938.

National Anti-Syphilis Committee—Gen. John J. Pershing has accepted the chairmanship of a National Anti-Syphilis Committee organized by the American Social Hygiene Association to further the campaign against venereal diseases. Dr. Ray Lyman Wilbur, president of Stanford University, California, is vice chairman and Mr. Charles H. Babcock is chairman of the executive committee. A drive for funds to finance the campaign will be made beginning Feb. 2, 1938, which has been designated the second National Social Hygiene Day.

Academy of Tropical Medicine—The fourth annual dinner of the Academy of Tropical Medicine will be held in New Orleans December 2, at La Louisiane Restaurant during the meeting of the Southern Medical Association. Dr. George C. Shattuck, Boston, will be toastmaster and Dr. Wilbur A. Sawyer, director of the International Health Division of the Rockefeller Foundation, New York, will give his presidential address on 'The Importance of Environment in the Study of Tropical Diseases.' The first award of the Theobald Smith Medal will be made by Col. Charles F. Craig, New Orleans, past president of the academy, to Marshall A. Barber, Ph.D., of the staff of the International Health Division of the Rockefeller Foundation, New York.

Jacobi Fellowship for Women Physicians—The Women's Medical Association of New York offers the Mary Putnam Jacobi Fellowship of \$1,000 for one year's graduate work in the medical sciences. The fellowship is open to any woman graduate of an approved medical school, who must be endorsed by the head of the department in which her previous work has been done. The recipient must give full time to the problem selected and should preferably make the study abroad, if she is not a resident of the United States; she should preferably study in the United States. Applications for the 1938-1939 fellowship should be filed before April 1, 1938, accompanied by statements as to health, educational qualifications and the proposed problem for investigation to the chairman of the fellowship committee, Dr. Annie S. Daniel, 321 East Fifteenth Street, New York.

Society News—Dr. Samuel B. Scholz, Jr., Philadelphia, was elected president of the Association of Life Insurance Medical Directors at the annual meeting in New York, October 28. Dr. Harold H. Mitchell, Long Island City, N. Y., was chosen president-elect of the American Association of School Physicians at the annual meeting in New York in October. Dr. John Sundwall, Ann Arbor, Mich., is president. Drs. Fredrika Moore, Cambridge, Mass., and James F. Rogers, Washington, D. C., were elected vice presidents and Dr. Arville O. DeWeese, Kent, Ohio, reelected secretary. Dr. Willard C. Rappleye, dean of the College of Physicians and Surgeons, Columbia University, New York, was chosen president-elect of the Association of American Medical Colleges at its meeting in San Francisco in October. Dr. William S. Middleton, Madison, Wis., was elected vice president and Dr. Fred C. Zapffe, Chicago, remains as secretary. Dr. Alan M. Chesney, Baltimore, was installed as president.

Medical Bills in Congress—*Changes in Status*. S. Res. 194 and H. Res. 352, submitted by Senator Copeland, New York, and by Representative Chapman, Kentucky, have been agreed to respectively, by the Senate and the House, requesting the United States Department of Agriculture to transmit to the Senate and House information with respect to the deaths incident to the use of Elixir of Sulfanilamide. *Bill Introduced*. S. 3008, introduced by Senator Davis, Pennsylvania, proposes to amend the existing laws against unlawful restraints and monopolies so as to provide that nothing in such laws shall prevent persons engaged in commerce from granting differentials in the prices of commodities sold to, or sold for resale to, and actually resold to, any corporation organized and operated exclusively for religious, charitable, scientific, literary or educational purposes, or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private shareholder or individual, and no substantial part of the activities of which is carrying on propaganda, or otherwise attempting to influence legislation.

Society of Tropical Medicine—The thirty-third annual meeting of the American Society of Tropical Medicine will be held in New Orleans November 30-December 3 in conjunction with the Southern Medical Association. Dr. George W. McCoy of the U. S. Public Health Service will deliver the second Charles Franklin Craig Lecture on 'The History of Leprosy in the United States.' Other speakers at the sessions some of which will be held jointly with the National Malaria Committee, will include:

Dr. Lee Foshay, Cincinnati: Serum Treatment of Tularemia
Dr. William M. James, Panama: R. P. Emetine Therapy
Dr. George C. Shattuck, Boston: Clinical Syphilis in the American Indian

Drs. M. Ruiz Castaneda and J. Vargas Carriel, Mexico: D. F. Skin Test for the Detection of Typhus Susceptibles

Drs. Noel Paul Hudson, Columbus, Ohio, and Edwin H. Lennette, Chicago: Incidence of Polioclonal Serums in Regions Where Polio myelitis Epidemics Are Infrequent

Dr. Richard P. Strong, Boston: Bartonella Infection

Dr. Herbert C. Clark, Panama, R. P., will deliver his presidential address at a luncheon December 1 at the Broussard Restaurant on 'Development of International Transportation and Its Effect on the Practice of Medicine.'

Prize to Inventor of Cyclotron—Ernest O. Lawrence, Ph.D., professor of physics, University of California, Berkeley, received the Comstock Prize of the National Academy of Sciences at the annual meeting in Rochester, N. Y., in October for his development of the cyclotron. The Comstock Prize, which carries an honorarium of \$2,500, is awarded every five years to the bona fide resident of North America who shall have made in the judgment of the academy, the most important discovery or investigation in electricity or magnetism or radiant energy. With the cyclotron, an apparatus in which rays of enormous energy are produced, Dr. Lawrence has been able to break up atoms and transmute them into other atoms, some of which are radioactive. At the academy meeting Dr. Lawrence reported that a new cyclotron is being built in which even more powerful rays will be formed; it will weigh 220 tons. The new machine will be used both for research on transmutation of elements and for medical and clinical research on the possible curative values of the various types of radiation. It is reported Dr. Lawrence, who is 36 years old, is a native of South Dakota. He graduated from the University of South Dakota in 1922 and took his doctorate at Yale University in 1925. He was appointed associate professor of physics at California in 1928 and became professor in 1930.

Annual Report of the Red Cross—Measures to reduce the heavy toll of accidents and relief rendered during the flood in the Ohio and Mississippi Valley last January were the high points in the experience of the American National Red Cross

during the fiscal year ended June 30, according to the annual report just issued. First aid training was widened, 256,884 certificates having been issued, an increase of 34,191 over the previous year, 81,291 were issued in life saving. Emergency first aid stations were established at 2,513 points and plans had been made for 3,283 more. In view of the fact that home and farm accident fatalities outnumber all other types of accidental deaths, the Red Cross began in 1935 a home and farm accident prevention program. The report states that 1,776 chapters requested material for such programs and that check lists showing hazards of homes and farms were distributed to seven million homes. Medical and health services were especially important during the January flood and the New London, Texas, school disaster, as well as in the period following the spring tornadoes in the South in 1936. Special hospitals were set up for flood victims stricken with influenza and pneumonia during the flood and in Arkansas an emergency hospital was established to cope with an epidemic of cerebrospinal meningitis. The report lists 1,035,764 visits by 666 public health nurses, of which 234,515 were maternity visits and 425,543 visits to the sick. The Red Cross classes in home hygiene and care of the sick gave certificates to 54,830 students. The financial statement shows that the Red Cross had assets amounting to \$19,782,279.28 as of June 30. During the fiscal year it had expended \$25,984,999.28, which included contributions for relief during the Ohio and Mississippi flood amounting to \$25,312,167.70, said to be the largest fund ever received for disaster relief during peace time.

FOREIGN

Anatomical Society Meeting—The forty-fifth annual meeting of the German Anatomical Society was held in Königsberg, East Prussia, August 25-28. Dr. Ross G. Harrison, Sterling professor of biology, Yale University School of Medicine, New Haven, Conn., was president and acted as chairman of all sessions. Drs. Charles C. Macklin, London, Ont. and Allan L. Grafflin, Boston, were among the participants in the meeting.

Consulting Centers for Rheumatism—At the International Congress on Rheumatism and Hydrology, to be held in Oxford, England, March 26-31, there will be an exhibition of plans for consulting bureaus for rheumatic patients, according to present plans. If there is sufficient interest and if funds can be obtained, prizes may be offered. For details apply to Dr. J. F. L. van Breemen, Keizersgracht 489, Amsterdam, Holland.

Government Services

Changes in U S Public Health Service

Dr. John T. McNabb, assistant surgeon, reserve corps for active duty, U S Hospital for Defective Delinquents, Springfield, Mo.
Dr. Wixom S. Sibley, assistant surgeon, regular corps, U S Marine Hospital, Mobile, Ala.
Dr. Carl V. Morrison, assistant surgeon, reserve corps, U S Public Health Service, Springfield, Mo.
Dr. Andrew B. Steele, assistant surgeon, reserve corps, Lewisburg, Pa.
Dr. Frank A. King, surgeon, reserve corps, U S Marine Hospital, New York.
Dr. Thornton L. Waylan, assistant surgeon, reserve corps, U S Marine Hospital, Cleveland.
Dr. James F. Spindler, assistant surgeon in the reserve corps for active duty at the U S Public Health Service Dispensary, Washington, D. C.
Dr. Lucius A. Salisbury, assistant surgeon, reserve corps for active duty, U S Marine Hospital, New York.

Colonel Tuttle Named Medical Director of United Air Lines

Col. Arnold D. Tuttle, medical corps, U S Army, for four years commandant of the School of Aviation Medicine, Randolph Field, Texas, has been appointed medical director and chief flight surgeon of United Air Lines. Colonel Tuttle will retire from the army. In his new position he will personally supervise the physical fitness of the company's flying personnel and will carry on research projects dealing with the promotion and maintenance of safe flying as far as the human element is concerned. According to a report from the United Air Lines, the company will provide space at its operation headquarters at the Chicago Airport for Colonel Tuttle's research department. Colonel Tuttle, who is 57 years old, graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1906.

The Physician of the Future

In an address to a meeting at Leeds, held as part of the national health campaign, Lord Horder said that inevitably the physician's work in the future will be more and more educational and less and less curative. More and more he will deal with physiology and psychology and less and less with pathology. He will spend his time keeping the fit fit rather than in trying to make the unfit fit. And we must make it worth his while to do this work. This reorientation of his education and his work is overdue, and it will remain overdue until reorientation takes place in the attitude of the health authorities toward him and toward his sphere of usefulness. And we must not think that his education is finished for all time when he becomes qualified. It is a duty we owe to every doctor to get him back now and again to the stimulating and informing atmosphere of the wards and the laboratories and, no less helpful, to the atmosphere created by his colleagues and teachers.

This means of course spending more money, but Lord Horder could not conceive how money could be better spent, and as a long term investment he believed it would pay over and over again. It was at the periphery and not only at the center where energy and knowledge were required. The physician was the expert who made contact with the individual and acted as the conducting medium between the individual and the facilities afforded by the health services through the local authorities. And not only the health services, there was the important matter of physical training and recreation. Grants were good and sergeant majors were useful, but the physician's training was essential to the proper use of physical methods in the production of national fitness. And so also in the equally important matter of the proper selection and the proper preparation of food. If economics had let us down—and it seemed as though it had—medicine must do what it can to hold the fort until economics came once more to its help.

Increase of Functional Nervous Diseases

While modern sanitation has greatly diminished or extinguished epidemic diseases such as plague, cholera, smallpox, and typhoid, the stress of civilization has greatly increased functional nervous diseases. It is only in recent years that a hospital, the Tavistock Clinic, devoted entirely to the treatment of these diseases, has been established. So great has been the demand on its services that a request for \$1,500,000 is being made so that it can erect larger premises. The duke of Kent, who is president, took the chair at the British Medical Association House, where an appeal was made for funds. Sir Farquhar Buzzard, professor of medicine in the University of Oxford, said that at least one third of all the sickness in this country was due to causes which were not organic in origin. About 50 per cent of the 15,000,000 insured population of England and Wales "went on the panel" every year and over 31,000,000 weeks of working time was lost annually by industrial sickness alone. A conservative estimate was that the neuroses and psychoneuroses were annually responsible for the loss of 10,000,000 weeks of working time. If he should be placed at the head of a great business organization, the first thing he would do would be to take on a whole time medical psychologist to study his employees and their conditions in health and deal with all cases of nervous disorder as they arose. The sick roll would rapidly diminish, the certificates of debility, gastritis and anemia would gradually become almost unknown, and the efficiency and happiness of the staff would be enhanced.

Lord Hollenden (industrialist) said that their most urgent problem had been to meet the demands for treatment of those who could not afford the full private fees or any fees at all. The ultimate solution of the nation-wide problem of psychoneurotic illness must lie largely in supplementing medical education, for at present there were not enough physicians who had acquired the special knowledge and skill in treatment which were needed for these conditions. The teachers in this branch of medicine were mostly in London for the moment, and consequently most of the training of graduate students must be carried out there. As provincial centers got the staff and establishment which they needed, the problems of providing treatment and doing preventive work would come nearer solution.

The Protection of Food Against Poison Gas

The government is taking the most minute precautions against attacks on this country by poison gas. The latest is the issue of a pamphlet for producers, manufacturers and distributors of foods regarding protection against contamination by poison gas in time of war, which has been issued by the Air Raids Precautions Department of the Home Office. It is pointed out that foodstuffs, for the most part, absorb gas readily and, if badly contaminated, would have to be destroyed. The protection afforded by different types of packing materials is stated. These range from containers, such as hermetically sealed glass bottles or cans, which when undamaged give complete protection, to ordinary sacks, such as are used for flour or grain, which give almost no protection. It is recommended that if it is necessary in an emergency to stack foodstuffs in open dumps or depots they should be covered by large tarpaulins. Open stores of grain or fodder should be similarly protected.

There are also hints for shopkeepers. When an air raid warning has been received, the shop should be completely closed up to keep out poison gas. Close fitting doors, windows or shutters will be required. Stocks should be stored in such a way as to prevent any gas that may enter the shop from penetrating to the food. All supplies should be kept as long as possible in their original packing and further protection given by keeping them in cupboards, drawers and boxes instead of on open shelves. These precautions would be necessary throughout a war, as the period of warning before an air raid is likely to be short. The protection of food in private houses will be dealt with in a handbook for householders, now being prepared.

"A Blot on London Medicine"

The medical schools of England for long worked in isolation. One of the great achievements of Lord Moynihan was to break down this isolation in the case of the surgeons by founding first a surgical club and then the Association of Surgeons of Great Britain. A similar service for medicine was done by Osler and others in founding the Association of British Physicians. But much more remains to be done. In his Harveian oration, delivered to the Royal College of Physicians, Sir Arthur Hurst recalled that he was the 281st orator who officiated on St. Luke's day in commemoration of the famous physician of King Charles I. He reviewed the recent advances in the physiology of the stomach and their bearing on our new knowledge of the causation and treatment of microcytic and macrocytic anemia and subacute combined degeneration of the cord in which he himself has had an important part. In the past the international relations of the college had been limited. It was still a blot on London medicine that there was so little intercommunication between the staffs and students of the twelve teaching hospitals, in striking contrast to the University of Paris, where students were free to attend clinics and lectures in any hospital they pleased. Visitors from the dominions and America generally knew more about the methods of teaching and the day to day work of the London hospitals than the hos-

pital physicians themselves, who were satisfied to continue their activities in far from splendid isolation. He suggested that the college might renew old associations with the schools of Padua and Leyden, where so many of their seventeenth and eighteenth century fellows received the greater part of their medical education, and enter into relations with the American College of Physicians, whose fellowship was open to Canadians.

Development of the Oxford Medical School

Graduates of the ancient universities of Oxford and Cambridge generally complete their medical training at the London hospitals, as the hospitals in Oxford and Cambridge are small and therefore limited in material for clinical teaching. But the munificent gift of \$1,000,000 from Lord Nuffield (the automobile magnate) has rendered great advances possible at Oxford. Professors of surgery and of obstetrics and gynecology are to be appointed, and new wards for their use are to be added to the Radcliffe Infirmary, with operating and x-ray amphitheatres. A new wing is to be added to the maternity of the hospital. Lord Nuffield has also offered the university \$5,000,000 with a site of the approximate value of \$500,000 for a college for graduate studies. Lord Nuffield's gifts are without precedent in the history of the university. Facilities for clinical research are to be organized which will be at least equal to those provided in the various scientific departments of the university.

The British Medical Association and Precautions Against Air Raids

The British Medical Association is taking steps to make a survey of the medical profession with a view to ascertaining how many physicians in each area would be likely to be available in such emergencies as air raids and in what capacity, having regard to their engagements and experiences. To this end physicians will be circularized and asked to state whether they would be prepared to offer their services on the understanding that they will have an opportunity every year of restating their wishes.

PARIS

(From Our Regular Correspondent)

Oct 30, 1937

Opening of Hospital of the Foch Foundation

Reference was made previously to a large hospital under construction in a Parisian suburb as a memorial to the late Marshal Foch. The hospital was opened for the reception of patients October 19, in the presence of Marshal Foch's widow, the president of the French Republic and his cabinet. The corner stone of this latest addition to hospital resources here was laid in 1931, but progress in its construction was delayed by lack of funds. The majority of the funds (80 per cent) has been donated by Americans as a token of the ties which bind France and the United States. One of the most active workers here in raising the funds was Mrs. Jacques Balsan (nee Vanderbilt). The new hospital is eleven stories high, includes a central and two lateral wings, and has a capacity of 340 beds and a wing for 100 nurses. The operating and sterilizing rooms occupy the top floor, and the lower floors contain wards and private rooms. All rooms of the hospital are provided with facilities for air conditioning.

The aim of the organizers of the hospital is to take care of the middle class public (students, teachers, artists, government employees and large private corporation clerks) who cannot afford to enter a private hospital or go to one of the many public institutions in Paris. The official title of the new hospital will be Mount Valerian Medical Foundation because a Foch Foundation already exists in Paris. The new hospital is located just across the Seine from the Bois de Boulogne, the great public park here, in the suburb of Suresnes on the flanks of Mount Valerian.

Pulmonary Reactions to Vaporized Solutions

At the July 27 meeting of the Academie de medecine a report was read by Bianchi and Delaville of some experimental work on the effects on the lungs of the inhalation of various vaporized solutions. In a previous report read at the January 26 meeting the authors stated that chemical particles in suspension in a gaseous atmosphere when inhaled passed beyond the lung and could be demonstrated in the urine. In the second series of experiments, rabbits and guinea pigs were provided with a gas mask or placed under a 5 liter bell jar. The following solutions in the form of a vapor were then introduced and allowed to escape at the top of the bell jar: suspensions of colloidal iron, oily emulsions, isotonic and hypertonic saline solutions and distilled water. The animals were killed at intervals varying from immediately after the experiment to six days. On microscopic study of the lungs, two types of effects were noted. 1. Following the inhalation of the vaporized colloidal iron suspensions and oily emulsions, a slight edema of the alveolar epithelium and inclusion of the iron particles or droplets of oil was noted. 2. With the isotonic and hypertonic saline solutions, a widespread hyperemia is noticeable. In both cases a variety of tissue reactions, slight to intense, takes place in the pulmonary alveoli. The reactions take place within a few minutes after the vaporization experiment is begun.

These observations, according to the authors, may clear up some still obscure points regarding certain respiratory attacks like those seen in asthma and in fogs. They also are instructive in calling attention to the potential dangers of drugs in vapor form which may have a strong irritant action on the pulmonary alveoli. Caution must be exercised in giving these treatments, just as in the case of short wave currents.

Spirochetal Jaundice as an Occupational Disease

At the July 27 meeting of the Academie de medecine a paper was read by Janbon and his associates on an epidemic of spirochaetosis ictero haemorrhagica in twenty-three miners. The pulpified kidney, liver and spleen of 125 rats (*Mus decumanus*) captured in the mine were inoculated into guinea pigs according to the Martin and Pettit technic, all with negative results. The sero-agglutination test, however, revealed a latent "spirochetose inapparente" form of the disease in 20 per cent of the inoculated guinea pigs. Search for spirochetes in the mud and on the walls of the galleries of the mine were negative. None of the miners had been bitten by the rats, but investigation revealed the fact that their food had often been contaminated by the rats and also that many of the miners had drunk the water in the lower galleries of the mine.

Prof Emile Sergent Retires from Public Hospital Work

One of the leading internists of Paris, Prof Emile Sergent, has reached the age limit and will be obliged to give up teaching in the large public hospitals here. His wards in the recently torn down Charite Hospital were the center of attraction for many of the younger men, who have since attained high rank in the profession. Professor Sergent is especially well known as a phthisiologist and has frequently been the guest of medical societies in all parts of the world.

Homage to Professor d'Arsonval

An admirer and friend of Professor d'Arsonval, professor at the College de France and internationally known as a leader in the field of electrical research, has just written his biography, under the title "Sixty Years of Science." d'Arsonval is now 86 years of age and came to Paris from central France in 1873. He entered the laboratory of Claude Bernard while still a medical student, and after the great physiologist's death he was appointed assistant to his successor, Brown-Sequard. In 1881

a special laboratory of biophysics was created for d'Arsonval and later he succeeded Brown-Sequard in the chair of medicine in the College de France. During the World War he was active in the munitions service and in 1925 was made a grand officer and later was given the grand cross of the Legion of Honor.

His research work on high frequency currents has made d'Arsonval known all over the scientific world. His name will always be associated with the perfection of high frequency apparatus as employed in medicine.

BERLIN

(From Our Regular Correspondent)

Oct 11, 1937

Distribution of German Physicians in 1937

A statistical report on the number and distribution of German physicians in the year 1937 has just appeared in the *Deutsches Aerzteblatt*, organ of the German Physicians' Association. The total number of physicians has increased in comparison with 1935 from 52,342 to 55,259. This increase is in part ascribable to the fact that information with respect to members of the medical profession is more readily obtainable under the new regulations.

As in former years, the geographic distribution of physicians within the German reich was found to be disproportionate, the number of physicians to each 10,000 of population varies from a minimum of 48 to a maximum of 158 (the latter figure represents Berlin). The 3,000 newly listed physicians were distributed rather evenly throughout the reich exclusive of Berlin. In the years 1933 and 1934, after the emigration of numerous Jews, the number of Berlin physicians underwent no small decrease, but it rose again subsequently and would have attained the 1932 level had not the law which forbids settlement of new doctors in Berlin supervened (there were 6,785 physicians in Berlin in 1932, 6,713 in 1937).

All members of the medical profession belong in one of the following five principal classifications:

Directors of institutions	4,608
Physicians on the staff of institutions but below the rank of director (assistants)	9,153
Physicians in government employ health officers confidential insurance consultants physicians engaged only in research and so on	5,000
Physicians professionally inactive	3,500
Independent practitioners	37,522

The sum of the foregoing figures will be found to exceed the actual total number of physicians because of certain duplications of classification, for example, the director of an institution or a doctor employed by the government may at the same time maintain a private practice. Of the "directors," approximately one third are, in addition, officials of health departments and so on, senior physicians of hospitals and university professors.

The number of doctors who can be classed only as directors of hospitals and other institutions for the sick amounts to 3,292, about 28 per cent of these are surgeons, 18 per cent internists and 7 per cent gynecologists and neurologists. Of physicians in governmental employ, more than 21 per cent still maintain private practice. The number of professionally inactive physicians increased from about 2,000 in the year 1935 to about 3,500, chiefly as a result of improved means of identification through compulsory registration. The figures show no increase in the number of independent practitioners. The number of insurance physicians has undergone a slight decline, owing no doubt, to the stricter prerequisites of admission to panel practice.

The number of specializing physicians amounts to 15,680, namely, 28.4 per cent of all physicians against a corresponding figure of 30.7 per cent in the year 1935. Double designations such as 'specialist in surgery and gynecology' or 'specialist in dermatology and urology' are no longer permitted; mention of a second specialty must not be made. A specialist may of

course continue to maintain a general practice. Of those specializing physicians who formerly used the designation "specialist in surgery and orthopedics," approximately one half chose to retain the style "specialist in surgery," the other half that of "specialist in orthopedics." This new ruling on nomenclature has exercised a certain influence on the computations with regard to the specialties in 1937.

Percentage of the Total Number of Specializing Physicians

	1937	1935
Internists	16.1	16.5
Surgeons	15.3	10.0
Gynecologists	10.6	9.8
Dermatologists	11.1	11.3
Otorhinolaryngologists	10.0	9.6
Ophthalmologists	8.6	8.5
Pediatricians	7.4	7.3
Neurologists and psychiatrists	10.1	10.2
Phthisiologists and other specialists in diseases of the lung	3.3	3.1
Gastrologists	1.2	1.2
Urologists	0.0	1.1
Orthopedists	2.3	1.6
Specialists in oromaxillary diseases	0.9	1.0
Roentgenologists and radiologists	2.2	2.0

The number of women physicians has increased from 3,379 in 1932 and 3,644 in 1935 to 4,339 in 1937. Whereas the total number of physicians showed in 1937 a 5.6 per cent increase over 1935, the number of women physicians increased by 19.1 per cent.

Women Physicians in 1937 (in Percentages of All Women Physicians)

Class of Physicians	1937	1935	1932
Independent practitioners			
(a) In general practice	35.7	48.8	52.5
(b) In the specialties	15.5	19.4	21.4
Employed	21.6	24.2	21.8
Professionally inactive	17.0	7.6	4.3

According to the foregoing figures in the table of women physicians, the number of women in private practice, and particularly the number of those in general practice, has undergone a further decline. Nearly one third of the women physicians are employed, 225 of these occupying positions in various public health services. Of specializing women physicians nearly one half are pediatricians, second in numerical rank are the gynecologists, and next follow the ophthalmologists and the internists.

A special chapter of the report deals with Jewish physicians. In the new register of physicians all those who under the "Nuremberg Laws" are considered Jews are specially listed as such. On the other hand the so called hybrids, namely, half-Jews and quarter-Jews, receive no special racial designation in the register. There are 4,220 Jewish physicians registered, they constitute 7.7 per cent of all physicians within the Reich. If only practitioners are counted, then of 37,525 doctors, 3,748 (that is about 10 per cent) are Jews. Of the Jewish group, 408 are engaged in neither private nor insurance practice. In the larger cities there are 3,179 Jewish doctors practicing medicine and of this number 1,710, or 53.8 per cent, are specialists. Among Jewish physicians the specialties of predilection according to the statistics are dermatology and venereology, internal medicine, gynecology and pediatrics. Besides the Jewish doctors, 350 'hybrids' are physicians and in addition there are 210 doctors officially listed as 'of Jewish affinity' namely non-Jewish men whose wives are Jewish. Members of the first named group are excluded from the insurance practice along with the non-Aryan doctors. One pair of Jewish grandparents in the ascendancy of a physician is sufficient basis for exclusion from insurance practice.

Alcoholism Among School Children

Dr. Johannsen, public health official of Hechingen (Württemberg), elicited some surprising data from his investigation of the indulgence in alcoholic beverages by school children of the community. He found that drinking among the young was quite common throughout the district, 75 per cent of the school children were accustomed to consume alcoholic beverages and 19 per cent did so daily. Of the 5,207 school children, it was possible to question all but sixty. In 923 instances, children affirmed that even younger brothers and sisters already partook of alcoholic drinks.

New wine, the beverage most commonly consumed, is known to possess a fairly high alcoholic content. The second most frequently consumed beverage was beer. Wine, properly speaking, was the beverage named in 108 instances, spirits in forty-eight instances. Twenty children stated that they had been intoxicated on several occasions. Some remedial measures for this state of affairs were to be instituted.

Collaboration of the German Red Cross in the Fight Against Disease

The German Red Cross, according to its constitution, is committed to the fight against epidemic and other disease. The central depot of the Red Cross in Berlin-Neubabelsberg serves as the base of supplies. Here are kept, for emergency use in time of epidemics or disasters of any sort, a huge number of portable hospital and living barracks of the Doecker type. These portables are collapsible and can be shipped in packing cases. They are 15 meters long by 5 meters wide and are double walled. Special foundations are unnecessary, as the floors are adjustable. A portable together with all its necessary furnishings (bedsteads, mattresses, bed linen, towels, night-stands, buckets, water pitchers, wash basins and so on) can comfortably be transported in an ordinary railway coach and unloaded in a few hours at a siding. Recently a new service of motor trucks (owned by the railroads) has been introduced for shorter hauls. This transport service is available on Sundays as well as on week days. The setting up of the portables is entrusted to a specially trained mounter and together with the aid of local agencies the entire process of installation requires but a few hours. So called sickness contracts are entered into in advance between the Red Cross and the party to whom the portables are lent, in this agreement are defined the responsibilities of both contracting parties relative to the quite formidable costs of installation and maintenance.

Oct 16, 1937

International Medical Week

The third International Medical Week in Switzerland, like the first and second weeks promoted by the *Schweizerische medizinische Hochschrift*, was held at Interlaken in September. Attendance was even greater than at the previous congresses, about 400 delegates were present. This congress too was officially sponsored by the federal government of Switzerland. Federal Councillor Dr. Etter, minister of public instruction, delivered the inaugural address. The management of the congress as in other years was in the hands of Prof. Alfred Gigon of Basel.

The first scientific lecture was delivered by Nobel prize winner Prof. Hans Spemann of Germany, his topic, "New Insight Into the Processes of Animal Embryology." A systematic causal analysis of the embryonal development of the Amphibia yields several data of fundamental significance which in their further implications may be related to important medical problems. The individual components of germinal cells in the Amphibia are not at first definitely conditioned to their later destiny, environmental influences select from out the rich

storehouse of organ-producing effects those which correspond to the locale. The germ cell is permeated with "fields of determination," which are retained, perhaps permanently. Normally they do not become perceptible because the exposed tissue is no longer capable of reaction to their influence. On the other hand, they are immediately demonstrable if one brings under this influence the embryonal tissue with its rich generative powers. These observations are of fundamental interest for medicine and perhaps also for research on tumors. The second speaker was Prof. Arthur Stoll of Basel on "Recent Developments in the Chemistry of Digitalis Glucosides." Stoll has been an important contributor to our knowledge of the chemistry of substances containing digitalis, especially through his isolation of glucosides from both squill and *Digitalis lanata*. Recently Stoll has succeeded in isolating in crystalline form a genuine glucoside, the seed of *Strophanthus Kombe* (K-strophanthoside). This new glucoside decomposes under hydrolysis with acids into strophanthidine and strophanthotriose, which consists of cymarose and two molecules of dextrose. A third paper, on tularemia, was submitted by Prof. K. F. Meyer of San Francisco. The speaker provided an impressive description of his investigations of this disease among the wild rodents of California; his talk was illustrated by extremely interesting motion pictures. The Faculty of Medicine of Zurich University took this occasion to confer on Professor Meyer in recognition of his scientific achievement the honorary degree of Doctor of Medicine.

"Brain and Nerves" was the second day's topic. Veraguth of Zurich first provided a historical account entitled "Fifty Years of Surgery of the Spinal Cord." His point of departure was the pioneer operation for a tumor on the spinal cord performed by the English surgeon Horsley in 1887. The speaker referred in particular to the advances which have been achieved since that time in surgical procedure and in early diagnosis. Hugh Cairns of London then spoke on "Results Reported in the Treatment of Intracranial Tumors." He discussed the results of surgical treatment and enumerated the factors that have contributed to a lowered operative mortality and an improvement in late secondary results. The seat of the tumor is an extremely important prognostic factor, as Cairns illustrated with reference to different cerebral regions. Tumors situated in vital portions of the brain are not amenable to direct surgical intervention. Many such tumors, however, can be successfully treated by conservative surgery and by irradiation. A clearer concept of the limitations of the surgical approach to cerebral tumors that lie in the more vital portions will in future conduce to better neurosurgical results. Clovis Vincent of Paris next discussed the therapy of the subacute and the chronic brain abscess. A fourth paper was read by Herbert Olivecrona of Stockholm on surgical treatment of Meniere's disease.

The first speaker of the afternoon session was Nobel prize winner Otto Loewi of Graz, his theme being "The Chemical Transmission of Nervous Action." Loewi has previously demonstrated that the efficacy of a stimulus of the cardiac nerves comes about through liberation of certain substances at the nerve termination, which in its turn elicits nervous stimulus. Lately he has found that this phenomenon applies both to the sympathetic nerves and to the spinal nerves. The substances liberated are acetylcholine and epinephrine. It could be observed that the liberation of substances takes place at the nerve termination itself in the following manner: The nervous stimulus releases the substances from restraint, whereupon they become diffusible and therewith effective. The liberated substances have their point of attack directly on the reactive organ. These more recent observations of Loewi represent a new notable landmark in the progress of his work. Laruelle, director of the Centre Neurologique, Brussels, then spoke on the pathophysiology of asthma. He distinguished the central, peripheral and muscular types of asthma. On this differentiation he bases

his therapeutic principles. The final speaker of the day was Iselin of Basel, who discussed rheumatism and the sympathetic. He attempted an explanatory outline of the whole problem of rheumatism.

The third day was dedicated to "General Problems." The first lecturer, the Basel gynecologist Labhardt, discussed the interrelation of obstetrics and the problems of population. He cited statistical records of the Woman's Hospital, Basel, which go back seventy years and more and which illustrate the strong influence of obstetrics on the census figures. In this connection he touched on the problem of birth control. Robert Rosle, pathologic anatomist of Berlin, then spoke on the familial behavior of tuberculosis and syphilis. Necropsy records of married couples and blood relations were systematically assembled and collated with respect to the problem of familial behavior of the two most important diseases of the people. Among the pertinent considerations is that of special organotropic strains of the causative organisms and of organic predispositions to attack. With respect to syphilitic married couples, the observation that the death of one spouse was usually followed after no great interval by that of the other led to the presumption of a similarity of agent. The high incidence of congenital syphilis among siblings was regarded in the same light. Yet, apart from rare exceptional instances, no evidence of an identity in the disease was manifested among marriage partners or in congenital syphilis as observed among siblings. On the whole, familial syphilis presents the same variegated and chequered picture as extrafamilial syphilis. With respect to tuberculosis, the necropsy reports on 162 married couples were compared, in these cases one or both of the spouses were tuberculous. The important datum was established that in fifty-nine cases of fatal tuberculosis in one partner the other partner did not succumb to the disease. This fact and instances of specially marked resistance among blood relatives indicate the possibility of a higher immunity against tuberculosis among human beings. Repetition in families of similarly located tuberculosis is rare (207 families were studied). An identity of pulmonary tuberculosis among siblings or among parents and children on the basis of Turban's classification is rejected by the author. A critical attitude was assumed toward the question of specific hereditary predispositions and a warning was sounded against overevaluation of hereditary-constitutional factors.

Wilhelm Falta of Vienna next lectured on the pathology of the thyroid. He pointed out among other things that diiodo tyrosine (3,5 diiodo-4-oxyphenylalanine) exerts only a thyroxine-like effect in myxedema if administered intramuscularly or intravenously in massive doses, in exophthalmic goiter, on the contrary, large doses of the same substances act like compound solution of iodine in that they restore to the thyroid the capability of the latter for storage of colloid and effective substance, a function temporarily inhibited by this disorder. Falta discussed the toxic effects of thyroid hormone, which may be present in the diencephalon and on account of which stronger doses of diencephalic narcotics exert favorable influences in exophthalmic goiter. Rudolf Nissen of Istanbul described his work in cardiac surgery with reference to heart wounds, valvular lesions (results extremely unfavorable), massive pulmonary emboli (operative treatment of this condition is so perilous that it should be resorted to only as a last resort), coronary sclerosis and the sequels of pericarditis. The clinical results of total thyroidectomy in cases of badly decompensated valvular lesions are good, although to be sure myxedematous manifestations may follow. K. F. Meyer of San Francisco then exhibited his excellent motion pictures on psittacosis and thus ended the day's program.

The fourth day's sessions were held at the clinics of the medical school in Berne. Emil Bürgi, pharmacologist, spoke first on the action of vegetable coloring matter on injured and

diseased skin In artificially produced lesions, chlorophyll shows itself superior to all other types of vegetable coloring matter Observations of patients with disease of the skin at the Berne Dermatologic Clinic have in general confirmed the earlier data

The theme on the fifth day was "Carbohydrate Metabolism" Leopold Lichtwitz of New York discussed disturbances in the regulation of carbohydrate metabolism The latter depends not only on the amount of the insulin secretion but also on the sensitivity to insulin of the organs affected The insulin value is however, not constant but is rendered variable by a group of factors and above all by the influence of the hypophysial-diencephalic complex The speaker cited several disorders in which the foregoing phenomena may be observed acromegaly, Simmond's disease, mesencephalitis, chronic arthritis and renal diabetes He further discussed disorders of the sympathetic nervous regulation Finally he considered the significance of blood sugar regulation in migraine and lipid nephroses and cited certain data with regard to spontaneous hypoglycemia H C Hagedorn provided a most impressive summary of his research on protamine insulin, with especial reference to his most recent studies Last of all, Georges Bickel of Geneva discussed spontaneous hypoglycemia, a problem with which he has been particularly concerned

On the final day of the congress, Hans von Meyenburg of Zurich lectured on chondrogenic skeletal diseases He has made a special study of the cartilaginous tissue His talk dealt principally with disorders in which a primary disease of the cartilage elicits reactions in certain portions of the osseous skeleton

BUDAPEST

The Annual Medical Week

Prof Baron Alexander Koranyi read a paper at the Annual Medical Week on the role of the circulatory system in growing old According to statistics of the Metropolitan Life Insurance Company, hypertension as a cause of death is four times as frequent as cancer Krehl in the first edition of his "Pathologische Physiologie" shows clearly how the vasomotor regulation of the blood stream spares the heart, lest the locally and transiently increased demand shall encumber that organ According to Thoma, the average weight of the heart increases from 316 to 331.8 Gm between the ages of 50 and 70 years According to Muller, the heart reaches the maximum weight, in proportion to the body weight, in women between 60 and 70 and in men between 70 and 80 The investigations of Muller on the hearts of old people showed that the weight of the musculature of the auricle in comparison with that of the ventricle continues steadily to increase from the thirtieth year of life

CORONARY THROMBOSIS AND TRANSITIONAL GLYCOSURIA

At the same meeting, Dr Lajos Horvay reviewed literature showing that some observers frequently found spontaneous glycosuria present in the acute stage of coronary thrombosis in nondiabetic patients He reported fourteen cases of coronary thrombosis in nondiabetic patients in whom transition—one day—glycosuria occurred in only one case He had occasion to observe this case for seven years, during which time the patient returned every six months with clocklike punctuality for control examinations, which proved that he was not diabetic In spite of this Horvay maintains the possibility that such glycosuria eventually may prove to be the manifestation of hidden diabetes The etiology of this condition is not clear Is it due to some functional or organic fault? Is it brought about by some transitory functional disturbance of the pancreas? Glycosuria occurs in only about 4 to 5 per cent of the cases of coronary thrombosis

AMAUROSIS AFTER PROLONGED USE OF QUINIDINE

Dr Braumüller reported a case in which a man, aged 54, suffered from frequent extrasystoles which, however, occurred only in the daytime The irregularity of the heart became so unbearable that once the patient attempted suicide After taking fairly large doses of quinidine for several years he noticed impairment of his eyesight An ophthalmologist found he was suffering from incipient amaurosis The patient died of an intercurrent pleurisy Braumüller said that amaurosis after large doses of quinidine may impair the vision and that no large doses should be prescribed In such cases the amaurosis may be due to spasms of the blood vessels, or be the result of a direct action on the ganglion cells of the retina To prevent the amaurosis, Strebel of Switzerland counteracts the vasodilating action of quinidine preparations by using as a vehicle for them light brandy or whisky, tea or coffee, which have a dilating effect on the cerebral vessels

WORK FOR CARDIAC PATIENTS

Dr Hasenfeld said that one of the important questions that have to be settled in the treatment of a patient with cardiac disease is the amount of work which he is able to perform It is the opinion of cardiologists that patients with compensated rheumatic heart disease are capable of more work than patients with similar degrees of cardiac syphilis or cardiosclerosis, because the former is a stationary lesion or at all events a less progressive lesion than the latter two Hasenfeld considered various occupations, and he concluded that no one kind of work can be recommended indiscriminately to cardiac patients but that each case must be gone into carefully in detail In his opinion, aortic regurgitation is compatible with good exercise tolerance (the cases he mentioned being rheumatic and not syphilitic) and also that in cases of mitral stenosis the exercise tolerance is good Naturally, in both those types of post-rheumatic heart disease the tendency is to a slow downward progress, so that the years of activity are in general shorter by several decades than those of the average healthy man Yet he mentioned the case of a woman who, acquiring aortic and mitral disease of rheumatic type at 23, led an active and useful life until she died at 54 Hasenfeld urged the adoption of the system used in America where heart clinics have been established in several large centers wherein the patient's capacity for work is tested After this a suitable employment is, if possible, found for the patient The value of such an organization is enormous The patient is all the better for the work, and so is the state, which gets a certain production from the man in exchange for supporting him

Marriages

ADLAI EWING STEPHENSON LILL, Richmond, Va., to Mrs Sarah Bugg Gholson in Henderson, N C, October 23

FRANCIS MARION DANIELS JR to Miss Frances Louise Schaefer, both of Greenville, S C, October 30

HENRY ALFRED BARRETT, New York, to Miss Rutli Silsby Marvott of Pawtucket, R I, in October

EDWARD SPENCER COWLES, New York, to Miss Lorraine Posey of Henderson, Ky, November 11

MAURICE L HORWITZ, Oakland Calif, to Miss Georgiana Lewis of San Francisco October 24

GORDON TAYLOR BURNS Chicago, to Miss Mildred Birmingham of Beryon, Ill, October 9

JAMES H HOLLIMON, Houston, Texas, to Miss Lora Sherman of Picayune Miss, October 6

CHARLES LOUIS GILBERT to Miss Minnie Fox Hopkins both of New York, October 23

ELAN MANSFIELD BARTON to Miss Jane Purvis High both of Chicago October 16

GLEN I ALLEN to Miss Dona Luke both of Peoria Ill September 25

Deaths

William Lincoln Noble ☉ Chicago, Rush Medical College, Chicago, 1888, member of the House of Delegates of the American Medical Association, in 1912, 1914 and 1915, an Affiliate Fellow of the American Medical Association, formerly member, advisory commission, Illinois Department of Registration and Education, past president of the Illinois State Medical Society and the Chicago Ophthalmological Society, at one time chief of staff of the Illinois Charitable Eye and Ear Infirmary, and superintendent of the Chicago State Hospital, on the staff of the West Side Hospital, past president and formerly member of the board of trustees of the University of Illinois, aged 76, died, October 14, at his home in Evanston, Ill., of bronchopneumonia

Louis Gross, New York, McGill University Faculty of Medicine, Montreal, Que., Canada, 1916 member of the American Association of Pathologists and Bacteriologists and the American Society for Experimental Pathology, director of laboratories of the Mount Sinai Hospital, in 1937 was awarded the bronze medal by the American Medical Association for an exhibit illustrating experimental studies on the blood supply to the heart in relation to coronary occlusion, aged 42, was killed, October 17, in an airplane accident

Henry Herbert Yerington, Palo Alto, Calif., Columbia University College of Physicians and Surgeons, New York, 1908, at one time associate clinical professor of pediatrics, Stanford University School of Medicine, San Francisco instructor in pediatrics at the Cooper Medical College, 1910-1911, formerly visiting pediatrician to the San Francisco Hospital and assistant on the visiting staff of the Children's Hospital, San Francisco, aged 57, died, August 30, in a sanatorium at San Jose

Nathan Winslow ☉ Baltimore, University of Maryland School of Medicine, Baltimore, 1901, professor of clinical surgery at his alma mater, member of the Southern Surgical Association, fellow of the American College of Surgeons, served during the World War, on the staffs of the University Hospital, Franklin Square Hospital and the West Baltimore General Hospital, aged 58, died, October 7, in St Luke's Hospital, Richmond, Va., of injuries received in an automobile accident

Arthur Betts ☉ Spokane, Wash., University of Illinois College of Medicine, Chicago, 1915, fellow the American College of Physicians, member of the American Roentgen Ray Society and the Radiological Society of North America, served during the World War, president-elect of the Washington State Medical Association, on the staffs of the Deaconess and St Luke's hospitals, aged 45, died suddenly, October 17

Elmer Burt Coolley ☉ Danville, Ill., Rush Medical College, Chicago, 1889, past president of the Illinois State Medical Society and the Vermilion County Medical Society, in 1918 member of the House of Delegates of the American Medical Association, for many years president of the Illinois Tuberculosis Association, aged 70, on the staff of the Lake View Hospital, where he died, October 12

Jonas Curtus Lyter ☉ St Louis, St Louis University School of Medicine 1907, member of the House of Delegates of the American Medical Association in 1922, 1924 and 1925, fellow the American College of Physicians, formerly assistant professor of medicine at his alma mater, on the staff of St Anthony's Hospital, aged 54, died, October 9, of heart disease

Frank J Schleier ☉ Omaha, John A Creighton Medical College, Omaha, 1904, associate professor of surgery at his alma mater, formerly county physician and city fire department surgeon, for many years on the staff of St Joseph's Hospital, aged 61, died, September 11, of coronary thrombosis, arteriosclerosis and diabetes mellitus

Robert William Bainbridge Mayo ☉ Baltimore Johns Hopkins University School of Medicine, Baltimore, 1903, formerly instructor in clinical medicine at his alma mater, served during the World War, medical director of the Home for Incurables, aged 53, died, October 21, in the Union Memorial Hospital, of esophageal constriction

Clinton Anthony Benzie, Chicago University of Illinois College of Medicine, Chicago, 1927, member of the Illinois State Medical Society, a physician for the child welfare bureau, city board of health, on the staff of St Margaret's Hospital Hammond Ind aged 40, was killed, September 8, when he was struck by an automobile

Francis William O'Connor, New York, M.R.C.S., England and L.R.C.P., London 1907, associate professor of medicine, Columbia University College of Physicians and Surgeons, associate attending physician to the Presbyterian Hospital, aged 53, died, October 3, following an operation for intestinal obstruction

Charles Wesley Worthen, White River Junction, Vt., University of Vermont College of Medicine, Burlington, 1893, Hahnemann Medical College and Hospital, Chicago 1894 aged 68, died, August 23, in the Mary Hitchcock Memorial Hospital, Hanover, N H., following an operation for appendicitis

Alexander Odell Snowden, Peekskill, N Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1877, member of the Medical Society of the State of New York, on the staff of the Peekskill Hospital, aged 83, died, September 20, of coronary thrombosis

Richard Bartlett Oleson ☉ Lombard, Ill Northwestern University Medical School, Chicago, 1893, fellow of the American College of Physicians, formerly county coroner, aged 67, died, August 6, at the Johns Hopkins Hospital, Baltimore, of benign prostatic hypertrophy and staphylococcal septicemia

Overton Hobart Swango, Jackson, Ky., Kentucky School of Medicine, Louisville, 1903, member of the Kentucky State Medical Association, served during the World War, aged 64, died, August 14, in the Veterans Administration Facility, Lexington, of arteriosclerotic heart disease

Erwin Golly MacFarland ☉ Utica, N Y., Baltimore Medical College, 1908, member of the American Urological Association, served during the World War, aged 52, on the staff of the Faxon Hospital, where he died, September 9, of mitral stenosis and myocarditis

Arthur Boyd Blinn, Loomis, N Y., Columbia University College of Physicians and Surgeons, New York, 1929, member of the Medical Society of the State of New York, on the staff of the Loomis Sanatorium, aged 33, died, August 30, of chronic pulmonary tuberculosis

Theodore P Livingston, Plattsmouth, Neb., Omaha Medical College, 1888, in 1909 a member of the House of Delegates of the American Medical Association, aged 73, died, September 7, in the Immanuel Hospital, Omaha, of coronary sclerosis and bronchopneumonia

Leon Edward Whetsell, Bloomington, Ind., Louisville (Ky.) Medical College, 1903, served during the World War, member of the police board, aged 57, died, August 23 in the Methodist Hospital, Indianapolis, of coronary occlusion and arteriosclerosis

Frederick William Delmage, Hermon, N Y., McGill University Faculty of Medicine, Montreal Que., Canada, 1897, member of the Medical Society of the State of New York, aged 66, died, August 16, of chronic nephritis and cerebral hemorrhage

William Charles Hands, Washingtonville, N Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882, aged 79, died September 8 of hypertrophic cirrhosis of the liver and chronic myocarditis

William Elry Caldwell ☉ Suffield, Conn., Baltimore Medical College, 1894, for many years served as a member of the town school committee, health officer, aged 67, on the staff of the Springfield (Mass.) Hospital, where he died, August 18

Frank Blinn Dorsey ☉ Keokuk, Iowa, College of Physicians and Surgeons, Keokuk, 1881, for many years on the staffs of the Graham Protestant Hospital and St Joseph's Hospital, aged 79, died, September 8, of chronic hepatitis

Thomas S Davis, Plainfield, N J., Hahnemann Medical College of Philadelphia, 1884 for many years on the staff of the Muhlenberg Hospital, aged 84 died, September 12, of cerebral embolism, chronic prostatitis and duodenal ulcer

William Jacob Shenberger, Windsor Pa., Jefferson Medical College of Philadelphia, 1904, member of the Medical Society of the State of Pennsylvania, aged 61, died August 20, of cerebral hemorrhage and carcinoma of the esophagus

William S Bentley, Sioux Falls, S. D., Hahnemann Medical College and Hospital, Chicago, 1893, member of the South Dakota State Medical Association, on the staff of the Veterans Administration, aged 66, died, August 29

Carl McLain Vermillion ☉ Pratt Kan Tulane University of Louisiana School of Medicine, New Orleans 1925 formerly county health officer, on the staff of the Ninnescah Hospital, aged 40, died, August 12 of nephritis

Everett Elmer Speaker ☉ Lake View Iowa State University of Iowa College of Homeopathic Medicine Iowa City

1897, formerly member of the state conservation commission, aged 60, died, August 30, of coronary sclerosis

Vernon Stevens Wilkinson, Cardiff, Md., University of Maryland School of Medicine, Baltimore, 1901, aged 63, died August 31, in the William Beaumont General Hospital, of nephritis, pulmonary tuberculosis and uremia

Elmer Dwight Strong @ El Paso, Texas, Hahnemann Medical College and Hospital, Chicago, 1901, aged 63, died August 31, in the William Beaumont General Hospital, of nephritis, pulmonary tuberculosis and uremia

William Spencer Ryan, Chicago, Rush Medical College, Chicago, 1895, also a dentist, served during the World War, aged 68, died, October 23 in the Veterans Administration Facility, Hines, Ill., of cerebral hemorrhage

Charles St V Zimmerman, Asheville, N C., National University Medical Department, Washington, D C., 1895, aged 68 died, August 17, of coronary thrombosis and colon bacillus infection of the urinary tract

Eljah Sherman Lake @ Chicago, Loyola University School of Medicine, Chicago, 1921, aged 50, on the staff of the Peoples Hospital, where he died, August 22, of chronic myocarditis and hypertension

William C Stirling, Sulphur Springs, Texas, Atlanta Medical College, 1884, past president and secretary of the Hopkins County Medical Society, aged 82, died, August 14, of cerebral hemorrhage

Solon W Merrill, Flushing, N Y College of Physicians and Surgeons, Baltimore, 1907, aged 56, died, September 15, at his home in Huntington, of hypertrophy of the prostate and pulmonary embolism

Helen West, Meriden, Conn., Boston University School of Medicine 1896, member of the Connecticut State Medical Society, aged 69, died, August 22, of cerebral hemorrhage and lobar pneumonia

August F G E Oberbeck, New York, New York Homoeopathic Medical College and Hospital, 1905, aged 69, was found dead, August 27, of coronary sclerosis and chronic myocarditis

Henry Hobert Bradley, Attica, N Y Albany (N Y) Medical College 1892 veteran of the Spanish-American War, aged 67, died, September 19, of chronic myocarditis and bronchitis

Walter Holmes Oliver, Monroe, N Y University of Pennsylvania Department of Medicine Philadelphia, 1909, aged 53 died, August 19, of chronic nephritis and chronic myocarditis

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Pfeiffer's Hamburg Tea—Fort Wayne Drug Co., Fort Wayne Ind. Composition Essentially plant drugs principally senna with small proportions of fennel and anise seed Represented as 'An Unfailing Preventive of Influenza' Fraudulent therapeutic claims—[N J 25054 July 1936]

Golden Chemical Compound—International Chemical Co Topeka Kan. Composition A dark reddish brown watery solution consisting of iron salts (ferric and ferrous sulfate) For diphtheritic and scarlet fever sore throat, pyorrhea erysipelas, eczema female disorders etc Not 'the most powerful germicide known' Fraudulent therapeutic claims—[N J 25061 July 1936]

Pinkham's Tablets—Lydia E. Pinkham Medicine Co. Lynn Mass. Composition In each tablet 1½ grains of sodium monobenzy succinate and 2 grains of an extract of a plant drug such as viburnum For menstrual disorders Fraudulent therapeutic claims—[N J 25062 July 1936 and N J 25837 January 1937]

Hildebrand's Gall Stone Capsules—Frank Granzow Mfg. Chemists Chicago Composition Essentially phenolphthalein oleic acid soap menthol sodium salicylate and plant fiber For gallstones gallbladder and stomach disorders etc Fraudulent therapeutic claims—[N J 25066 July 1936]

Granzow's Tonic Tablets—Frank Granzow Mfg. Chemists Chicago (Supplementing Hildebrand's Gallstone Capsules) Composition Essentially sodium sulfate an iron compound and a small proportion of strychnine coated with lime carbonate and sugar For debility nervousness sleeplessness etc Fraudulent therapeutic claims—[N J 25066 July 1936]

Kurlene Eyelash Grower—Kurlash Co. Rochester N. Y. Composition Essentially mercuric oxide salicylic acid and petrolatum with a small amount of vanillin For granulated lids as well as for growing eyelashes Fraudulent therapeutic claims—[N J 25067 July 1936]

Prescription No. 69—Home Drug Co. Minneapolis Composition Essentially glycerin with small amounts of oxgall and bile acids For gallbladder trouble gallstones and liver disorders Fraudulent therapeutic claims—[N J 25070 July 1936]

Antiseptic Capsules—DeVore Mfg. Co. Columbus Ohio Composition Essentially common salt borax baking soda salicylic acid volatile oils including cinnamon thymol and menthol with red coloring matter For tonsillitis laryngitis ulcerated throat and mouth etc Not antiseptic Fraudulent therapeutic claims—[N J 25077 July 1936]

Special Treatment for Diabetis [sic]—DeVore Mfg. Co. Columbus Ohio Composition Essentially Rochelle salt and water flavored with cinnamon oil Fraudulent therapeutic claims—[N J 25077 July 1936]

Gold Seal Vegetable Compound for Women—DeVore Mfg. Co. Columbus Ohio Composition Essentially extracts of plant drugs including berberis and laxatives with a benzoate, a salicylate saccharin phosphoric acid alcohol (14 per cent by volume) and water For female disorders Fraudulent therapeutic claims—[N J 25077 July 1936]

Dovola Carbolic Salve—John J. Smith trading as Dovola Co. Chicago Composition Carbolic acid (3 per cent) in an ointment base For sores ulcers itch etc Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Ointment Zinc Oxide—John J. Smith trading as Dovola Co. Chicago Composition Zinc oxide (not more than 17½ per cent) For inflammations such as eczema Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Throat Gargle—John J. Smith trading as Dovola Co. Chicago Composition Small proportions of ferric chloride and potassium chlorate in a mixture of water and glycerin Fraudulently represented as an effective treatment for sore throat—[N J 25078 July 1936]

Dovola Wild Cherry Expectorant—John J. Smith trading as Dovola Co. Chicago Composition Essentially extracts of plant drugs glycerin sugar and water For coughs croup bronchitis etc Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Vegetable Laxative Tablets—John J. Smith trading as Dovola Co. Chicago Composition Extracts of plant drugs including nuxvomica Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Special Tonic Pills—John J. Smith trading as Dovola Co. Chicago Composition A phosphide was found For purifying the blood and restoring "shattered nerve forces" Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Eczema Ointment—John J. Smith trading as Dovola Co. Chicago Composition A yellow semi solid containing bismuth subcarbonate zinc oxide and sulfur in an ointment base Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Special Pills—John J. Smith, trading as Dovola Co. Chicago Composition Extracts of plant drugs and salt peter For Bright's disease, diabetes gallstones leukorrhea, gleet etc Fraudulent therapeutic claims—[N J 25078 July 1936]

Dovola Creol—John J. Smith trading as Dovola Co. Chicago Composition Water soap phenols, glycerin and a small amount of neutral oils Skin cure Fraudulent therapeutic claims—[N J 25078 July 1936]

Shavegrass Cut—Regina Rieppel trading as Miss R. Regina New York Composition Cut equisetum (horsetail) For kidney and bladder disorders ulcers, cancer etc Fraudulent therapeutic claims—[N J 25079 July 1936]

Healdline Health Salts—John J. Smith trading as Dovola Co. Chicago Composition Essentially baking soda (28.5 per cent) epsom salt (21.3 per cent) cream of tartar (22.4 per cent) tartaric acid (17.9 per cent) sodium phosphate (8.8 per cent) and starch (1.4 per cent) For biliousness, boils, pimples, rheumatism etc Fraudulent therapeutic claims—[N J 25078 July 1936]

LaClyde Lemon Vegetable Soap—Clyde Collins Chemical Co., Memphis Tenn. Composition Chiefly sodium soap and a fluorescent dye For pimples and other skin disorders Not antiseptic Fraudulent therapeutic claims—[N J 25082 July 1936]

Ru Co. Female Tonic—Clyde Collins Chemical Co. Memphis Tenn. Composition Essentially water alcohol sugars, plant extracts (bearing valertanic acid) and a small amount of iron and benzoic acid Fraudulent therapeutic claims—[N J 25082 July 1936]

Hygeen Tablets—John B. Petrie trading as the B. V. Laboratories and the Purity Products Co. Chicago Composition Baking soda tartaric acid and small amounts of silica, starch and an organic chlorinated product such as chloramine T. Fraudulently represented as a vaginal germicide—[N J 25093 July 1936]

Cholax Brand Pulvis Effervescens Salts Phosphatis Comp. (Kelvan)—George T. G. Duke and Mary W. Lambert, trading as Crescent Kelvan Co. Philadelphia Composition Granular material consisting of sodium phosphate anhydrous (15.8 per cent) sodium sulfate anhydrous (19.6 per cent) epsom salt anhydrous (10.6 per cent) and an effervescent base of baking soda, citric and tartaric acids. Fraudulently represented as a remedy for rheumatism and stomach, liver and kidney disorders—[N J 25094 July 1936]

Ru Co. Wonderful Health Laxative—Clyde Collins Chemical Co. Memphis Tenn. Composition Chiefly dehydrated Glauber's and epsom salts For sallow skin pimples blotches abnormal weight etc Fraudulent therapeutic claims—[N J 25082 July 1936]

B. X. Special Multi Strength Treatment—John B. Petrie trading as the B. V. Laboratories and the Purity Products Co. Chicago Composition A brown liquid containing chiefly apio and a small amount of ergot For menstrual disorders Fraudulent therapeutic claims—[N J 25093 July 1936]

B. X. Monthly Relief Compound—John B. Petrie, trading as the B. V. Laboratories and the Purity Products Co. Chicago Composition Pills chiefly containing iron sulfate aloe ergot and a terebinthinate oil resembling oil of savin For female disorders Fraudulent therapeutic claims—[N J 25093 July 1936]

B. X. Menstrua—John B. Petrie, trading as the B. V. Laboratories and the Purity Products Co. Chicago Composition Capsules and tablets the first containing apio and a small amount of savin oil and the second containing extracts of plant drugs including a laxative For female disorders Fraudulent therapeutic claims—[N J 25093 July 1936]

LaClyde Lucky Bleaching Ointment—Clyde Collins Chemical Co. Memphis Tenn. Composition An ointment containing ammoniated mercury (3 per cent) For pimples tetter eczema etc Fraudulent therapeutic claims—[N J 25082 July 1936]

Kellogg's (Dr. J. D.) Asthma Remedy—Northrop & Lyman & Co. Inc. Buffalo N. Y. and Toronto Composition Powdered plant material including stramonium Fraudulent therapeutic claims—[N J 25078 July 1936]

Freses Hamburg Tea—Coffin Redington Co. San Francisco Composition Essentially ground plant material including senna lavender and coriander For indigestion dyspepsia blood and skin ailments due to constipation etc Fraudulent therapeutic claims—[N J 25093 July 1936]

Nature's Mineral Food—Nature's Mineral Food Inc. and Perry B. Smith Indianapolis Composition Essentially the phosphate carbonate and chloride of calcium with epsom salt common salt and small amounts of iron sulfate potassium iodide sodium salicylate and free sulfur For blood stomach and kidney disorders diabetes arthritis high blood pressure etc Fraudulent therapeutic claims—[N J 25091 July 1936]

Correspondence

THE SCARLET FEVER PATENTS

To the Editor —The special article entitled "Medical Patents" published in the November 6 issue of THE JOURNAL implies that the Scarlet Fever Committee has interfered with research through its methods of administering the patent on scarlet fever toxin and scarlet fever antitoxin. In reply to this implication and the author's statement that such effect is probably due to the personnel of the committee, it should be stated that application for a patent was not made until after receipt of the following letter from the director of the National Institute of Health, and after consultation with the Council on Pharmacy and Chemistry of the American Medical Association, which concurred in the advice given in this letter

TREASURY DEPARTMENT
United States
Public Health Service
Washington D C
November 12 1924

Dr Geo F Dick
% John McCormick Institute for Infectious Diseases,
637 South Wood Street Chicago Illinois

Dear Doctor Dick —

I am amplifying somewhat my telegram of this date in reply to yours sent from Columbus Ohio yesterday

Some months ago when the streptococci acquired new interest in relation to scarlet fever we stated to licensed manufacturers in response to inquiries that in our opinion there was no objection to marketing packages of antistreptococcus serum for which license was held in such way that it would indicate that the scarlet fever type of organism had been utilized in the immunization of the animals. It is possible that we were in error in this but as I said in my telegram I believe it would be necessary to have a legal decision to settle this point

I am sending you a copy of the Biologies regulations and in the back of the pamphlet you will find the law there is nothing in the law which actually enables the government to prevent the placing of unlicensed preparations on the market the law however provides adequate penalties for violation and is enforceable through the usual court proceedings the action I take it being brought in the United States court

The more we have considered the requirements which you feel should be met the more we have been impressed with the difficulties of commercial production just at present Dr Dyer and I feel that the best and perhaps the only way to comply completely with your requirements would be for yourselves to take out patents on your preparations handling the patents in any manner you see fit. This would give you the opportunity to permit the manufacture in any limited number of places in accordance with your own judgment. I take it that there is no difficulty in this from the ethical point of view because according to our understanding this is just what was done by the Toronto group of research workers in connection with Insulin

With kindest regards I am

Very truly yours

G W McCoy
Director

After decision to act on Dr McCoy's suggestion, the Secretary of the Council was asked if the Council would consent to administer the patent. The answer was in the negative. He was then consulted as to the desirability of assigning the patent to a university, to a research institute or to a committee and advised the formation of a committee for the purpose of administering the patent as Dr McCoy had suggested. When approached on the advisability of granting an exclusive license, as had been done in the case of the insulin patent, he pointed out that while an exclusive license would greatly simplify the problems of administration, it would work undeserved hardship on unlicensed manufacturers and give the possessor of the exclusive license an unearned advantage, that it would also prevent the unlicensed manufacturers acquiring experience in the manufacture of products which they would eventually be expected to furnish

In accordance with this advice, the Scarlet Fever Committee when organized decided to offer licenses to all reputable commercial manufacturers licensed by the United States Public Health Service on exactly the same terms and to grant free licenses to health departments, although this decision involved the maintenance of a much larger and more expensive organization for testing products from all manufacturers than would have been required for testing the products of one exclusive licensee

In order to avoid price fixing and still ensure the lowest cost to the public consistent with good quality, the royalty was fixed at 5 per cent instead of the 10 per cent charged by the Insulin Committee. For some time this low fee did not furnish enough income to cover the cost of testing the numerous samples submitted by the various manufacturers. On the other hand, competition and the fact that, by reducing the price of scarlet fever products to physicians, the manufacturers were able to reduce the amount paid to the Scarlet Fever Committee, while the service they received from the committee in testing their products remained the same, resulted in the new scarlet fever materials which were more costly to manufacture selling as cheaply as diphtheria products on which there was no patent

Any implication to the effect that the Scarlet Fever Committee has interfered with research is wholly unjustified. The fact that the committee has not hampered research should be apparent to any one conversant with recent literature. In no instance has the committee suggested that even poorly conceived research by incompetent investigators be discontinued. Improvements have promptly been adopted. When fallacious results have been published, the committee has been content to meet them by scientific articles calling attention to the fallacies if they seemed of sufficient importance

An example of the freedom the scarlet Fever Committee has allowed in the field of research is furnished by the fact that the Massachusetts State Health Department, a licensee of the committee, is still distributing for the purpose of statistical research formalized scarlet fever toxin under the name of "scarlet fever toxoid." This is permitted despite publication by two members of the Scarlet Fever Committee in THE JOURNAL (Nov 3, 1934) of adequate and unrefuted evidence showing that such preparations contain no toxoid and despite the poor results the material has given in the four year trial

The Scarlet Fever Committee is heartily in accord with Dr Fishbein's suggestion that a responsible and unbiased group be formed to administer all medical patents. Such an arrangement would give uniformity in methods of administration, would relieve the discoverers of onerous duties which now interfere with further research they might accomplish, and would be an advantage to manufacturers who at present are obliged to deal with a different group for each patent under which they operate

THE SCARLET FEVER COMMITTEE

COMA IN INSULIN-HYPOGLYCEMIC THERAPY OF SCHIZOPHRENIA

To the Editor —Recent literature discussing the insulin-hypoglycemic therapy of schizophrenia indicates some confusion as to what is understood by the term coma. It is of clinical importance to have some gauge as to the onset of coma and its optimum depth. Dorland defines coma as a state of complete loss of consciousness from which the patient cannot be aroused even by the most powerful stimulation. Sakel states (Am J Psychiat 94 111 [July] 1937) that 'coma should be associated with the absence of the corneal reflex or at least with presence of a Babinski. Cameron and Hoskins (THE JOURNAL, Oct. 16 1937, p 1246) differ. They say "We usually consider somewhat arbitrarily that coma is present when the patient can no longer swallow, when, if he is turned on his side saliva tends to drool from the mouth, or when, on the eyelids being drawn up, the eyeball is found to be wandering slowly in the orbit." We read in 'A Study of Hypoglycemic Shock Treatment in Schizophrenia' by Isabel G H Wilson, M.D., 'When the corneal reflexes disappear, the patient is considered to be in coma. Loss of the light reflex of the pupil is usually regarded as an indication for the interruption of shock'

According to our own experience we have found it very difficult to say exactly when the patient was in coma. Many patients who cannot be aroused show persistent corneal and swallowing reflexes and no Babinski. Often when the swallowing reflex was gone and a variable Babinski appeared, the corneal reflex persisted. Again, drooling of saliva and free moving of the eyeball are often found before the appearance of the Babinski or loss of the corneal reflexes. When the complete absence of the corneal reflexes, however, is taken as the criterion, we have found it impossible to produce coma in many patients of the chronic type when large doses of insulin are required.

Disparities in the efficacy of the hypoglycemic treatment may well be due to different interpretations in the meaning of the term coma.

MORRIS W. BRODY, M.D.
MAX HAYMAN, M.D.
Springfield State Hospital,
Sykesville, Md.

SUGGESTIONS FOR THE POSITION FOR COMATOSE INSULIN SHOCK PATIENTS

To the Editor—The treatment of coma in insulin shock resembles surgical narcosis in several respects, one of them being the danger of aspiration of mucus due to increased secretion of saliva and the absence of pharyngeal reflexes. It is an established fact, known for generations, that aspiration in surgical narcosis is best prevented by placing the patient in a flat position, head turned, so as to permit the saliva to flow out of the mouth.

In view of that fact, it seems strange that the half upright position has been recommended for comatose insulin shock patients in some recent publications (Wilson, Isabel G. H. A Study of Hypoglycemic Shock Treatment in Schizophrenia, Board of Control, H. M. Stationery Office, 1937; Cameron, D. E., and Hoskins, R. G. Experiences in the Insulin-Hypoglycemia Treatment of Schizophrenia, THE JOURNAL, October 16, p. 1246) and doubtless in earlier papers from which they are partly compiled.

Seeing no reason to neglect precautions generally accepted in surgery, we have been placing our patients at the Neurological Hospital in a perfectly flat position, head turned, as soon as they go into coma. Our experiences have been quite satisfactory. Therefore we propose this procedure for general use in insulin shock therapy.

G. WILSE ROBINSON JR., M.D.
HEINRICH LANN, M.D.
Kansas City, Mo.

From the Neurological Hospital (the Robinson Clinic Inc.)

LETTERS OF FIELDING H. GARRISON

To the Editor—The publication of a volume of selected letters of Fielding H. Garrison is being considered. It is felt that such a volume will not only be welcome to the many friends of Garrison but will constitute a real contribution to American literature. It will present to a larger public a brilliant writer who so far has been known only to a limited group consisting mostly of medical men.

Mr. F. L. Trietsch, who was an intimate friend of Garrison, will edit the volume. Mr. Henry Mencken and I are to contribute forewords.

I wish to invite all the many correspondents of Garrison to send their letters to the Institute of the History of Medicine, Johns Hopkins University, 1900 East Monument Street, Baltimore. The letters will be copied in the institute and the originals will be returned to their owners without delay. The copies will be preserved in the institute as material for a future biography.

While Garrison was very reserved in personal contacts, he was exuberant in his letters. His moods and whatever worried

him found expression in letters. Letter writing was his way to free himself from oppressing thoughts and he not seldom passed harsh judgments on matters and people. It is needless to say that the editor will proceed very carefully in selecting the letters or passages from letters to be published.

HENRY E. SIGERIST, M.D., Baltimore

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF THE TABETIC FORM OF DEMENTIA PARALYTICA

To the Editor—A man aged 56 years has the tabetic form of dementia paralytica. Twenty years ago he was treated for tabes by the Swift Ellis method. He was given six treatments and discharged as improved when he refused to continue. He had no further antisyphilitic treatment until six years ago. At that time he developed acute manifestations of dementia paralytica and was given neosphenamine followed by spinal fluid drainage for a period of three months. His spinal fluid showed the typical gold curve of dementia paralytica as well as a positive Wassermann reaction. The blood Wassermann reaction was also positive. He refused further therapy until November 1936, when he came under my care. He had just returned from a fishing trip with 147 turkeys and was negotiating for the purchase of a whale. He complained of lightning pains in his legs and frequent attacks of paroxysmal tachycardia. His family noted personality changes and loss of judgment. Examination revealed Argyll Robertson pupils, absent knee jerks, a positive Romberg sign and extreme nervousness. The blood Wassermann reaction was 4 plus. The spinal fluid Wassermann reaction was 4 plus, and there was a positive Pandy test and a 5555541000 gold curve. The urine was normal and the hemoglobin 90 per cent. I gave him 10 cc of mixed tertiary malaria blood intravenously which was followed by chills in ten days. Treated at home he had twenty-seven temperature rises, sixteen of which reached 106 F for at least four hours each. After the first chill his lightning pains disappeared and have not returned. After six chills auricular fibrillation set in which was adequately controlled with digitalis. The malaria was interrupted with quinine late in December 1936. The urine was normal, the hemoglobin 40 per cent. Mentally he was worse than ever. January 1, 1 Gm of trypanamide was started increasing to 3 Gm weekly, with a routine weekly check of the visual fields for the first seven weeks. There was no loss of vision and no further checks have been carried out. He has now had seventeen injections of trypanamide. He received in addition six injections of 2 cc each of iodobismutol beginning January 1. The urine showed 2 plus albumin and many casts which cleared when the bismuth was stopped. Neosphenamine was started March 23 with 0.15 Gm increasing to 0.6 Gm weekly. The trypanamide and neosphenamine are given from three to four days apart. The urine continues negative, the lightning pains are gone. The tabetic gait is improved and he no longer falls with the Romberg test. He has had only two mild attacks of paroxysmal tachycardia since the start of his malaria and there has been no recurrence of the fibrillation. Mentally he has improved progressively until now he is apparently normal in his business judgment and social contacts. My tentative plans are to continue therapy as follows: two more injections of 0.6 Gm of neosphenamine completing a course of 4.65 Gm followed by a bismuth compound again for a course of ten to twelve weeks if the urine remains clear. At the same time trypanamide is to be continued uninterrupted. I shall check the spinal fluid again in December. Potassium iodide is refused by the patient. 1. What further treatment should be carried out? 2. How long should the trypanamide be continued? 3. No cardiovascular check up by x-rays or fluoroscopy has been made, is this advisable? 4. The prognosis originally given the family was poor. What are the patient's chances now for a permanent remission with adequate therapy? 5. Is it likely that the paroxysmal tachycardia was due to the syphilis and if so does malaria help this type of lesion? Any other suggestions or comments will be most welcome.

ALBERT C. DANIELS, M.D., San Rafael, Calif.

ANSWER—1. It is suggested that the correspondent stop giving neosphenamine now and not repeat it. Neosphenamine has not proved to be efficacious in parenchymatous brain and spinal cord syphilis (dementia paralytica or tabes dorsalis). In other forms of neurosyphilis (meningovascular) it may be of no advantage.

2. Trypanamide should be used once every week for the next thirteen weeks with the same precaution regarding the optic nerve heads as well as the visual fields as before. No more trypanamide after this for at least eight to twelve weeks.

3. In order to determine the type of cardiovascular disease it is important to have a fluoroscopic, flat x-ray plate and electrocardiographic study of the heart.

4. It is impossible to give any definite prognosis. From the evidence submitted it seems reasonable to believe that the

treatment has been the responsible factor in bringing about the clinical improvement. If this is true, the ultimate outcome may be favorable for some time to come. It is not possible to cure absolutely either dementia paralytica or tabes dorsalis. If the cardiovascular and renal systems remain in a good functioning state, a new course of trypanamide (from 2 to 3 Gm every week) for from twenty to thirty weeks can be started after a rest period of from eight to twelve weeks. After this some form of bismuth or mercury can be given intramuscularly twice weekly for thirty weeks.

5 If the paroxysmal tachycardia is due to syphilis, malarial therapy is definitely contraindicated.

6 During the rest period some form of electrical hyperpæxia can be given. The patient should have from six to eight treatments in which the temperature is permitted to rise to 103 to 103.6 F for at least two to four hours. A treatment may be given every second or third day.

ANKLE CLONUS IN INFANT

To the Editor—An infant boy aged 3 months has shown for the past month a bilateral clonus usually voluntarily induced by the physician but at times involuntary and without pressure applied to the foot. The reflexes are slightly hyperactive the Babinski sign is positive and there are no other pathologic reflexes. The legs are not spastic and there is no limitation of motion. There was no instrumentation at birth which occurred after only four and a half hours of labor. There was no injury to the child at any time. The ankle clonus is becoming progressively worse. Please state the possible etiology, prognosis and treatment.

MD New York

ANSWER—In a child of 3 months the plantar reflex is of limited diagnostic value. Monrad Krohn found that during the first year of life 77 per cent of children had an extensor (Babinski) response. A bilateral Babinski sign at three months is therefore considered a normal response, supposedly because the pyramidal fibers (corticospinal tract) are not yet myelinated. Bilateral ankle clonus, however, is more suggestive of organic disease of these tracts, patellar clonus, if present would almost certainly indicate an organic lesion. Ankle clonus plus a bilateral Babinski response in this patient add weight to the suggestion of a structural lesion, but at 3 months of age no diagnosis based on these signs can or should be made. Especially is this true in view of the absence of spasticity or paralysis and the history of normal easy delivery. The disease most seriously to be considered in the future is infantile cerebral palsy (Little's disease). The increase in the ankle clonus is suggestive but not diagnostic of this condition. Any discussion on prognosis and treatment is not justified until the diagnosis is at least made clear. The child should be repeatedly examined at intervals of three months.

BLOOD SEDIMENTATION RATE IN PULMONARY TUBERCULOSIS

To the Editor—Can you explain the following to me? I have had at least ten cases diagnosed as early pulmonary tuberculosis. The diagnosis was determined by history, physical examinations and x-ray examination of the chest all in adults. The blood sedimentation rate was determined in all of them prior to treatment which consisted of confinement to bed, forced feeding, cod liver oil and calcium. All gained from 15 to 20 pounds (7.9 Kg.) the cough disappeared and x-ray examination showed a deposit of calcium about the area of infection. Now the thing I cannot account for is that they all show a decidedly more rapid sedimentation rate after treatment instead of a slower one as I should expect.

EUGENE C. LOWE MD Miami Fla

ANSWER—The red blood cell sedimentation rate may be definitely increased during the development of the primary complex and again when clinical tuberculosis is present. Wallgren (*Am J Dis Child* 49:1105 [May] 1935) has shown that when fever occurs during the development of the primary complex, it is of short duration usually it does not persist longer than two or three weeks. However the red cell sedimentation rate which is increased while the fever is present usually does not reach a normal level until several weeks after the fever has disappeared.

As all these patients showed deposits of calcium about the areas of infection one might infer that the lesions represented parts of primary complexes. While it is true that calcium may be deposited in the secondary or reinfection type of tuberculous lesions apparently it is not the rule whereas in primary lesions it is a frequent occurrence. Calcium deposits have been demonstrated in primary lesions as early as four months after the lesion begins to develop. However they usually do not reach sufficient size to be demonstrated by x-ray examination until a considerably longer time has passed. If the lesions in the ten patients were primary and calcium is already in evidence one would expect that in the absence of other causes of

increased sedimentation rate it would now have reached a normal level. If the lesions were of the secondary or reinfection type, it is not unusual for the sedimentation rate to continue at a definitely increased level over a considerable period after all other symptoms have disappeared and the x-ray shadows are stationary or have decreased in size. Symptoms and x-ray shadows are not always a reliable criterion with reference to activity of a tuberculous process. Symptoms usually disappear long before activity ceases. The x-ray shadow may definitely decrease in extent and yet within the lesion which casts the shadow or even outside the shadow active lesions may persist.

Another important fact that must be borne in mind is that tuberculous lesions are rarely single. Often multiple primary complexes are laid down in various parts of the body and the secondary or reinfection type of tuberculosis may develop in other organs preceding during or subsequent to the development of pulmonary lesions. Examination of most of the other internal organs for tuberculous lesions during life is difficult and therefore active lesions in one or more parts of the body may cause the sedimentation rate to remain increased long after the pulmonary lesion has ceased to be active. Increase in the red blood cell sedimentation rate is not specific for tuberculosis. Therefore nontuberculous infections involving other parts of the body may be responsible for the increase in the sedimentation rate.

GENERALIZED MUSCULAR TWITCHINGS

To the Editor—A man aged 25 has been under constant mental strain for about seven months. One evening before some important examinations he started having muscular twitches which have persisted for one month. The twitches may start anywhere in the thigh, neck or buttocks for example and then may reappear anywhere. Thus a muscle in the neck will twitch then one in the arm, leg, buttock or eye without any sort of regularity or rhythm. The twitch never lasts more than five seconds, disappears and reappears somewhere else on the body. Sometimes a large portion of the muscle is involved and sometimes only a restricted area. These twitches are subjectively perceived but never seem to hit exactly the same place twice. There has been no muscle wasting, weakness or atrophy. They always appear when the patient is muscularly inactive and never while he is doing something that requires muscular activity such as tennis. The Wassermann and Kahn reaction tests are negative and otherwise he is a healthy adult who is prone to worry. What is the nature, etiology and treatment of this condition? MS New York

ANSWER—Transient twitches or quivering of muscles known as myokymia affecting a few muscle bundles usually without movement of the joint, constitute a fairly common symptom in patients suffering from anemia or neurasthenia. The muscles commonly involved are those around the eye, the deltoid, biceps and triceps and the glutei and the quadriceps. It is characteristic for myokymia to occur when the muscle is not in active use.

There are many intrinsic diseases of the central nervous system in which myokymia is also a symptom but they are accompanied by atrophy, paralysis, changes in the electrical reactions or alteration of the deep or superficial reflexes. Myokymia is seen in progressive muscular atrophy, amyotrophic lateral sclerosis, syringomyelia, progressive bulbar palsy and a few other chronic intrinsic degenerative conditions of the spinal cord and medulla. There is no reason to believe from the history as stated that this young man suffers from any of these serious diseases. The condition will disappear if adequate attention is paid to the patient's neurasthenia or to his anemia if this is present.

MONGOLIAN IDIOCY

To the Editor—Have there been any new developments in the treatment of mongolian idiocy? The mother insists that the child's mental condition is due to a fall shortly after birth. May the fall be the exciting factor in bringing on this condition? The child is at present 9 years old and is kept at home. What do you think should be done with such a child? MD Florida

ANSWER—A great deal of effort has been made, especially by the endocrinologists, to devise some method of treating mongolian idiocy (or, better, imbecility) but nothing new has been devised. Institutional care is perhaps not as imperative in cases of this sort as in others but the social factors should always be taken into consideration. Most psychiatrists particularly those who deal with mental defectives, are familiar with the statement made by parents that the child's mental deficiency is due to a fall. This very likely is due to some wishful thinking that nothing in the heritage which they give to the child is responsible for the condition. Since the etiology of this type of mental deficiency is unknown it is impossible to say that the fall had no connection with it but since certainly 99 per cent of mongolian idiots are obviously such at birth it is highly improbable. As for the disposition of such a case the decision must lie with the persons concerned. If the child is a

menace in the community and it is difficult for the parents to control it, institutional care is indicated for the safety of all concerned. Another consideration which is very important is whether there are any siblings, brothers and sisters who go to school are likely to be taunted about having an imbecile in the family. A great deal more care is lavished on such a child, resulting in the neglect of the normal children. On the other hand, there are occasional cases of only children whose parents get a great deal of satisfaction out of caring for the defective child, and they do much more for such a child than could be done for him in an institution.

PYOMETRA

To the Editor—A white woman, aged 33 a quinquipara with five normal deliveries, was operated on nine months ago for a relaxed perineum, moderate prolapse of the right cystic ovary and a diseased appendix. The operation consisted of a diagnostic curettage (pathologic examination gave negative results) repair of the vaginal outlet, right salpingo-oophorectomy, left salpingectomy Coffey suspension of the uterus and appendectomy. Since the operation the patient has had a continuous discharge (before the operation she had no discharge) and profound continuous pain in the lower part of the abdomen mostly in the midline. The menses occur every three weeks last from six to seven days and contain large and small clots having a fleshy and at times putrid odor. Following the period the discharge is brownish for two or three days then greenish tinged and then a profuse yellowish mucoid purulent discharge requiring three or four napkins daily because of the discomfort of this acrid discharge. No special organisms or Trichomonas have been found. Examination revealed the perineum healed the cervix clean, hence the discharge must be coming from the body of the uterus. Bimanual examination was difficult owing to the obesity (200 pounds, 90 Kg) of the patient. However the uterus was freely movable but tender on palpations in fact, the whole lower part of the abdomen was tender. No masses were elicited. Please omit name.

M D Pennsylvania

ANSWER—The probable cause of the patient's profound pain in the lower part of the abdomen and the purulent vaginal discharge is a pyometra, or accumulation of pus, in the uterine cavity. This may be due to a stricture of scar tissue in the internal os or anywhere else along the cervical canal, the result of trauma of a strenuous dilation and curettage. The frequent menses may be due to interference in the blood supply of the ovary, which was not removed. This may be a temporary disturbance. The diagnosis of pyometra may be verified or disproved by inserting a probe or better still, a No 4 or 5 Hegar dilator into the cervical canal beyond the internal os. If a purulent discharge escapes, the diagnosis of pyometra is confirmed. The treatment consists in the insertion of a stiff rubber tube to permit drainage of the uterine contents. Of course, this procedure must be carried out under aseptic precautions. If purulent material escapes from the uterine cavity, the drainage tube should be left in place a few days. No anesthetic is necessary for the insertion of the probe or cervical dilator, but the patient should be given a narcotic before the procedure is carried out.

POSSIBLE TOXICITY OF ROTENONE INSECT DUST

To the Editor—Please advise as to the toxicity danger in the use of Rotenone Insect Dust by Hammonds on vegetables beans cabbage and cucumbers.

H H RITTENHOUSE M D Bridgeville Pa

ANSWER—Rotenone itself is seldom used as an insecticide, but rather the powdered crude root of Cube or Derris (containing rotenone, deguelin, toxicarol and tephrosin as the principal active constituents). As judged from animal (and to some extent, human) experimentation there is no danger of acute poisoning as a result of ingestion of vegetables sprayed with rotenone, cube or derris. In this connection it has been estimated that allowing for a maximum spray deposit and assuming that man is no more resistant than the most susceptible of the laboratory animals, a person would have to eat about 4,000 apples sprayed with derris to obtain an acutely fatal dose. The problem of a possible chronic intoxication following the prolonged use of vegetables treated with derris or rotenone has been studied on animals and, while further work is desirable, results of these observations also lead one to believe that the human health hazard here is also low. Hammonds Rotenone Insect Dust is said to be a stabilized rotenone product.

SHORT WAVE DIATHERMY IN ARTERIOSCLEROSIS

To the Editor—While I was giving a short wave treatment with induction coil on 25 meters—the coil in pancake fashion over the forehead—to an infected sinus in a man, aged 55 the patient within three minutes after the treatment was started suddenly had a severe convulsion with complete loss of consciousness. Following some heavy breathing the respiration stopped and the pulse could not be found. Before epinephrine could be administered respiration and heart action gradually returned and the patient after three quarters of an hour of unconsciousness slowly recovered. This was the patient's second treatment the first less tolerated without any difficulty. As the treatment had just begun the amount of heat created was moderate and the patient's statement after he had fully regained consciousness was that he felt slightly warm the last he could remember. The blood pressure was 200/120 a week prior to the treatment and 110/50 following the accident. With the exception of hypertension and a chronic sinus infection the patient's condition was normal. There was no history of similar attacks. What in your opinion happened and is this a common occurrence? Is hypertension or moderate arteriosclerosis a contraindication to treatment with the induction cable placed on the forehead?

M D, New York

ANSWER—Complaints of headache, nervous restlessness and slight fever by workers near the powerful short wave radio broadcasting tubes was the incentive for large scale research work in the therapeutic use of short wave radiation. During the past few years short wave diathermy to the sinuses and the brain by both condenser plates and by coil treatment has been extensively employed by investigators and clinicians. Search of the literature fails to disclose any reports of ill effect of such heat treatment. In animal experiments with the 15 meter wave applied to the brain (Horn, Kauders and Liebesny *Wien klin Wchnschr* 30 936 [July 27] 1934) necropsy showed a selective hyperemia of the meningeal blood vessels as compared with control animals. The same effect has been shown in necropsy of the brain of paralytic patients after a course of short wave treatments. In the case described the best explanation is a sudden heat effect causing a reactive spasm in presumably arteriosclerotic blood vessels. There appears to be no definite contraindication to short wave coil treatment to the sinuses in suspected arteriosclerosis of the cerebral vessels provided the patient is under constant observation and that the heating is increased gradually and is always kept within comfortable toleration.

POSSIBILITIES OF MENSTRUATION AND PREGNANCY AFTER IRRADIATION AND OVARIAN TUMOR

To the Editor—An unmarried woman aged 26 had marked menstrual discomfort since puberty and for two years previously had profuse bleeding at the menstrual period so that she was anemic and unable to do her work properly. In December 1932 600 roentgens was given over the right ovary and, as the profuse bleeding began again the following month 50.44 mg of radium was inserted into the uterus for sixteen hours in January 1933. This stopped the menstrual bleeding but she was told that it would not be permanent. Shortly after this a left ovarian tumor was diagnosed and removed and was found to be a dermoid cyst. At the same time a small wedge shaped section of the somewhat sclerotic right ovary was also resected. Owing to subsequent left kidney operations one for calculus and another within a few days because of stricture and ureteral obstruction from which she was not expected to recover because of the severe shock her health has been poor. Much of her difficulties were found to be due to a systolic pressure ranging between 65 and 90 mm of mercury. Appropriate treatment immediately raised this to 120 mm. she has gained 10 pounds (4.5 Kg) to a present weight of 116 pounds (53 Kg) and does not have the weak spells that had plagued her for six years. Has or has not this woman now 33 years old any chance of returning menses and of becoming pregnant? What plan of endocrine medication would be most likely to stimulate any remaining ovarian tissue? If she should become pregnant what are her chances of having a normal child? She is anxious to have children but will not marry with the present outlook.

M D, Pennsylvania

ANSWER—In spite of the lapse of four and a half years there is definitely a chance for the return of menstruation in this case. The reason for a fair degree of optimism is the patient's youth at the time the roentgen and radium treatments were given. In some instances much larger doses have been administered than this patient received and menstruation has returned after an interval of a number of years. On the other hand, in some young women a small amount of radiation therapy has resulted in a permanent amenorrhea. Unfortunately there is no way to foretell which young women will have a permanent absence of the menses and which ones will not.

It is possible for the patient to be ovulating even though she does not menstruate. A simple way to determine this is to remove small pieces of endometrium at weekly intervals with a tiny curet either with or without suction. This procedure may readily be performed in a physician's office without any anesthetic. If, on microscopic examination, repeated specimens show a stationary type of endometrium or atrophic tissue the patient is almost certainly not ovulating. If successive changes are found that reveal both proliferative and secretory endometrium, ovulation is probably taking place.

The only endocrine products that may stimulate ovarian function are those derived from the anterior pituitary gland or the gonadotropic substance derived from the urine of pregnancy. However, the results of such therapy have not been promising. If the patient should become pregnant and continue to full term, her chances for having normal children are just as good as those of women who have not received radiation therapy. There has been controversy on this subject but the consensus is that radiation therapy applied before fertilization of an ovum does no harm. On the other hand, when roentgen therapy or radium is applied after conception has taken place, distinct harm may result to the fetus.

ATTACKS OF EPIGASTRIC PAIN

To the Editor—A white woman aged 37 dates her illness from the birth of a child fifteen years ago. Three days after she had an attack of epigastric pain accompanied by nausea. There was no vomiting and no radiation of pain. Relief was obtained by morphine. This pain has persisted on and off for two years. Her appendix was removed with no effect. Roentgenograms of the gastro-intestinal tract were negative. One year later the gallbladder was removed and in six months the attacks recurred. The attacks could be relieved by morphine. There was hiccoughing and rarely vomiting. Between attacks she was perfectly well. Six years ago she was operated on for a right tubal pregnancy. Nine months ago she began to use a drug containing pantopon, papaverine and atropine derivative. Taken by mouth it does not give the help that she gets when it is dissolved in some water and instilled into the rectum. Two months ago a surgical exploration disclosed nothing except some adhesions which were broken. Three days later a typical attack occurred. Since then I have made numerous skin tests and had a gastro-intestinal series done. All were negative. Physical examination discloses some tenderness in the epigastrium. The blood pressure is 120 systolic 68 diastolic. The weight ranges from 137½ to 124 pounds (62.56 kg.) now. The Wassermann reaction is negative. Blood counts and urine examination give normal results. At present she gets two attacks a day, one of them waking her from sleep at night. She describes the pain as a muscle soreness. She has been loaded with antispasmodics and analgesics to no avail. She has been on low fat and elimination diets but the attacks occur just the same. Will you suggest a diagnosis or outline further studies and treatment?

M D New York

ANSWER—The pain is probably due to visceral spasm associated with some trouble in the sympathetic nervous system. A spinal Wassermann test should be done and, if this is negative, operation on the sympathetic ganglion might be considered.

RUSTED STEEL FROM SWEATING

To the Editor—With a local industry in which I am plant physician the following problem has arisen on which I should like your advice. Of a group of men who make a final inspection of equipment that must fit very closely some rust the finish in inspecting it. By fingerprinting them on similar steel surfaces I have found which ones are responsible for the rusting and this has been checked by their inspection output in the plant. In those men who rust the steel in their inspection I have found no physical abnormalities nor as far as I can ascertain are their habits different from those of their colleagues who do not rust equipment. Is there a difference in the secretions of the hands of different persons? Is this difference something that can be anticipated by suitable physical or laboratory examination prior to their employment? Can you suggest some way of correcting this rusting propensity of these otherwise good workmen?

M D Indiana

ANSWER—The chemical constituents of perspiration are not precisely the same for all persons, and the same person may demonstrate appreciable changes during different periods of the same day. Long continued profuse sweating produces a more alkaline sweat. Also as sweating is sustained, the output of sodium chloride and other mineral salts may be increased. The high output of sodium chloride is associated with metal rusting although this one chemical may not be the sole factor responsible. The use of rock salt on streets for antifreeze purposes has become a source of complaint in connection with the rusting of the steel of automobiles. In some plants it has proved desirable to make use of stainless steel in connection with mechanisms requiring close fittings and under other circumstances. It is not readily possible to determine, other than by trial and error, members of any work group who may contaminate metal by the products of perspiration. However, a number of avenues offer escape from this type of damage. In some instances rubber gloves may be worn to advantage. If this is not practical, a wide variety of chemicals may be utilized as sweat depressants. No one of these is entirely free from injury. Their use in industry merely substitutes minor physiologic damage for the damage that is done to steel parts through causing rust. Among other agents that may be used are aluminum chloride, aluminum acetotartrate, alum solution of formaldehyde, zinc oxide and titanium dioxide. Two typical formulas are: 1. Aluminum chloride 16 Gm. distilled water 100 cc., mix, filter and apply as a lotion. 2. Aluminum sulfate 32 Gm., potassium permanganate 6 Gm. water 100 cc., mix, dissolve and apply as a lotion.

MENSTRUAL PAIN AND CURE OF GONORRHEA

To the Editor—A young married woman complained of a moderate vaginal discharge and severe abdominal pain during her menstrual period. Examination showed that pus could be expressed from the para-urethral (Skene's) ducts and that there was a moderate degree of cervicitis. A blood test gave a negative Wassermann reaction but a positive 4 plus gonorrheal complement fixation. The assumption is that this patient has a chronic gonococcal infection of Skene's ducts and of the cervix. The husband gives a history of syphilis adequately treated prior to marriage but no history of gonorrhea. His blood is negative for both syphilis and gonorrhea. Would you kindly answer the following questions: 1. Does the infection account for the abdominal menstrual pain? 2. What is the most approved method of treatment especially of Skene's ducts? 3. How long will treatment be necessary to cure the condition? 4. What are the criteria for complete cure so that coitus may be indulged in without danger of infecting the partner?

M D New York

ANSWER—1. Pelvic pain associated with gonococcal infection may be present only at the time of menstrual congestion, but it is more characteristic of gonorrhea for the patient to have pain at other times also. Nothing is stated relative to palpable disease of the adnexa, if there is a pathologic condition sufficient to produce symptoms there is usually palpable thickening, or at least tenderness, in the region of the adnexa.

2. Skene's ducts, each 1 cm. in length and located in the floor of the urethra, are the rudimentary homologues of the prostate gland. They open on the floor of the urethra, just at or within the meatus. There are from two to four para-urethral glands near the urethral meatus. Real pus expressed from Skene's ducts is pathognomonic of gonococcal infection, but one must be careful not to confuse pus with innocent inspissated secretion, which may often be expressed from the duct orifices. Bristle-like thickening of the duct affords confirmatory evidence of gonorrheal disease. Many leading laboratories attach little importance to the gonorrheal complement fixation test. It is of uncertain value.

3. A woman who harbors the gonococcus tends gradually to rid herself of infection within a few months, provided she does not have a consort who is also infected, and provided further that she does not drink alcoholic beverages or indulge in sexual excesses. Traumatic local treatments during the active course of the disease tend to drive the gonococcus into the deeper tissues and prolong the infection.

4. There are no specific criteria for complete cure. Cessation of symptoms and absence of the gonococcus in smears and in cultures should be followed by a quiescent period of six months or a year, preferably the latter, before one can be assured of a cure. In all cases a search should be made for pockets of infection in Skene's ducts and in the cervix before the patient is discharged as cured.

TUBERCULOSIS OF HIP AND CONGENITAL DISLOCATION

To the Editor—I have a patient who probably had tuberculosis of the left hip in childhood. Be that as it may she has a pseudarthrosis of the left hip. The left lower limb is shorter but she bears her weight in walking pretty evenly on both sides. She does not favor one side. I take it that this makes the prognosis better. The left trochanter is somewhat atrophied and a little posterior to its usual position. With the pelvimeter that I have I find it difficult to measure the transverse diameter of the outlet. By internal examination I cannot make out any great deformity. The patient is eight months pregnant. The measurements are as follows: anterior superior spines 22 cm. crests 28 cm. trochanters 31 cm. right oblique 22 cm. left oblique 21 cm. superior conjugate 20 cm. anterior posterior of outlet (uncorrected) 12 cm. transverse of outlet 8 cm. posterior superior spine to opposite tuber ischia right 20 cm. left 17 cm. 1st lumbar to anterior superior iliac spine of same side right 21 cm. left 17 cm. posterior superior spine to opposite greater trochanter right 21 cm. left 25 cm. posterior superior spine to lower margin of symphysis of same side right 22 cm. left 21 cm. middle of back to posterior superior spine right 35 cm. left 5 cm. This case does not strike me as one of unilateral congenital dislocation. Please omit name.

M D Pennsylvania

ANSWER—The data supplied are insufficient to warrant any accurate diagnosis. The question of a dislocation of the hip should be verified by x-ray films. The limp presented by a patient with congenital dislocation of the hip results from the occurrence of the Trendelenburg sign when the weight is carried on the dislocated side, that is, the pelvis on the opposite side drops instead of having the normal elevation that should occur from the normal mechanism about the hip.

A tuberculous hip of long standing usually shows evidence of a destructive process which has involved the acetabulum, the head of the femur or both. There is evidence of cavitation of the involved areas and possible growth disturbances resulting from epiphyseal destruction. The motion in such a tuberculous hip is more apt to be restricted in all directions and at times may be painful. The prognosis for a normal delivery would seem most favorable. Undue strain on the involved hip should be reduced to a minimum and the possibility of a flare up of

a tuberculous condition must be kept in mind. In the event of this being a congenital dislocation, there should be no increase of symptoms unless the patient puts on considerable weight. A detailed x-ray study would seem most desirable.

BELCHING

To the Editor—A white man aged 37, complains of belching which is more severe at night for the past twelve years. It is so severe that his sleep is disturbed. He notices that certain foods increase the belching. There is no pain or tenderness present in the abdomen. The bowels are regular and the stools normal. He has a slight cough. No other symptoms are present. The family history is essentially negative. He has an executive position in a large concern demanding a great deal of responsibility. The patient is rather thin and somewhat undernourished. He weighs 122 pounds (55 kg.) and is 5 feet 7 inches in height. The scalp, eyes, ears and throat are normal. In the nose the turbinates are small and there is a wide gap between the turbinates and the septum, the result of a resection of the middle and inferior turbinates fifteen years ago. The neck and thyroid are not enlarged, there is no cervical adenopathy. The lungs and heart are normal. The blood pressure is 110 systolic, 75 diastolic. The abdomen, genitalia, rectum and extremities are normal. The skin is normal. The reflexes are equal and slightly hyperactive. The urine is normal. The hemoglobin is 75 per cent (Sahli). Red blood cells number 3,800,000, leukocytes 7,000 with the differential count normal. The Wassermann and Kahn reactions are negative. Gastric analysis is normal. X-ray and fluoroscopic examinations reveal a normal chest. Gastrointestinal x-ray examinations show only slightly increased peristalsis of the stomach and ptosis of the colon. Gallbladder studies give negative results. The diagnosis of aerophagia was made and explained to him. He was told to omit foods that disagreed with him and to eat slowly. Tincture of belladonna, a sedative and liquid petrolatum were given with no apparent relief. Any suggestions that you may give in relieving this condition will be greatly appreciated.

M D Ohio

ANSWER—Since the patient has a hemoglobin of 75 per cent (Sahli) and an erythrocyte count of 3,800,000, it is important that he be given iron. It is also important to remove gas-producing foods, such as members of the cabbage family and baked beans. Since the worst symptoms are at night, it is important that he sleep with a very thin pillow or preferably none at all. When he has a desire to belch he must hold his head up instead of leaning it forward, as he probably does now. Putting his head forward is a maneuver which makes him swallow more air. There is no gas produced in the stomach except in the presence of a high grade obstruction or when such substances as sodium bicarbonate are taken which combine with the hydrochloric acid to form carbon dioxide. He should always keep his head back when he has the desire to belch. Tell him to let what will come up by itself but that he must not try to get it up or keep it down.

ATTEMPTED STERILITY BY IMMUNIZING TO SPERMATOZOA

To the Editor—Some time ago I read an article on the production of temporary sterility in the female by injecting semen intramuscularly. Since the flood I have been unable to find the reference to this procedure. Kindly let me know the status of this procedure and give references to the original work.

M D, Ohio

ANSWER—Much experimental work has been done on animals to create a biologic immunity against spermatozoa. The injection into male rabbits either of their own semen or of a serum obtained from fowls into which rabbit semen has been repeatedly injected produces a marked depression of spermatogenesis. The subcutaneous injection of spermatozoa into female rats renders them temporarily sterile. In general, the immunity thus produced by spermatoxins is specific for the species but there are many exceptions to this rule, for the semen of the bull and the ram can immunize other animals, and the female rat may be sensitized by various sorts of semen.

Numerous workers have attempted to apply these results to the human female for purposes of contraception. In Russia it is the custom to use a preparation of human semen obtained from a condom specimen diluted with two parts of salt solution and to give from twelve to eighteen intramuscular injections in the buttocks twice a week, the amounts being gradually increased from 0.5 to 5 cc. No bad results have been observed. Baskin offers a simpler technic (*Am J Obst & Gynec* 24:892 [Dec] 1932).

The efficiency of the immunization is determined either by noting immobilization of spermatozoa in a hanging drop preparation or by a precipitation test. Ordinarily the result of one series of injections remains effective, both by laboratory evidence and according to clinical standards, from six months to a year.

One is forced to conclude that the value of this procedure as a contraceptive measure is still *sub judice*. The risks seem to be almost negligible, but the efficacy of the method cannot yet be fully evaluated.

HORMONE TREATMENT OF INFANTILE UTERUS

To the Editor—What product can I use to stimulate uterine growth? The patient in question has been diagnosed by injection of iodized oil as having an infantile uterus. Will she ever be able to conceive? She is 30 years old and has oligomenorrhea but no other trouble with her other bodily functions. The basal metabolic rate is minus 10. Please mention dosage and length of administration.

M D Cambridge Mass

ANSWER—Estrogenic products, such as theelin, theelol, amniotin, progynon-B, and progynon-DH and emmenon, are fairly satisfactory substitutes for ovarian activity, but they do not stimulate the ovary. Clinical use for troubles other than menopause symptoms and vaginitis in children is of doubtful value.

The pituitary gland of the living subject stimulates the ovary to activity, but clinically satisfactory gonadotropic products from the pituitary are not available for therapeutic use. Gonadotropic substance from the urine of pregnant women or from the placenta also stimulates the ovary, but it is doubtful that it would be of any significant use in this case.

OIL IN WATER

To the Editor—The water supply of this community is obtained from two wells about 250 feet deep. Bacterial examination shows no contamination. The water is fairly soft and of good quality. There is some oil in the water which varies from time to time from a very thin film to small droplets. This oil probably comes from several sources from the pumps in which case it would be plain lubricating oil from pipes and fittings used in the oil business in which case it might be crude oil or from the water strata owing to the practice of some oil companies throughout the oil field of forcing the water to the surface with natural gas under high pressure. I doubt that the latter is responsible for much of the oil in the water. What effect if any will this oil have on the human system? Would it cause rather severe cases of diarrhea?

L T Cox, M D Kermit Texas

ANSWER—Several areas in Texas possess drinking water supplies contaminated with oil. At the least, such water produces psychologic injury in the causation of nausea, in the curtailment of proper quantities of water intake and in general apprehension. Tourists through this section of the country on occasions report disturbing diarrheas, which are sometimes said to disappear on changing to bottled water for drinking purposes.

ALCOHOL INJECTIONS FOR PAIN

To the Editor—I should like information and references concerning the use of alcohol in the injection of the posterior sensory roots and the peripheral sensory nerves to relieve constant pain. I am particularly interested in the percentage of alcohol recommended for injection, the possible duration of the anesthesia and the untoward effects that might be expected.

C S FRANKLE M D St Petersburg Fla

ANSWER—Ninety-five per cent absolute alcohol is used ordinarily in injecting posterior sensory roots and for injection directly into peripheral sensory nerves. The relief of pain sometimes lasts as long as a year and a half. More frequently it is less than that, and often only nine months. The most common untoward result is painful neuritis, which may persist for weeks. If the alcohol is injected too superficially, slough may result or a sterile abscess may develop. Trauma from the needle striking a nerve trunk, or from pushing a nerve trunk against bone and injuring it, may be erroneously attributed to the alcohol. When a needle has been inserted at the wrong angle for paravertebral injection of a sensory root, the needle may be inserted through the intervertebral foramen and puncture the dura of the spinal cord. Too much alcohol injected into the spinal fluid may have a fatal result. Subdural injection of alcohol for relief of pain usually is carried out with from 0.5 to 1 cc of absolute alcohol. The complication to be avoided in this injection is paralysis.

CONGO RED IN TUMORS AND ROENTGENOLOGY

To the Editor—I am anxious to learn the details of the treatment of cancer with congo red. Can you outline the course of treatment? Where can I find the name and address of the doctors studying the drug?

F A NICOLETTI M D Pueblo Colo

ANSWER—The use of congo red was reported by Drs Isidore Arons and Boris Sokoloff at the fifth International Congress of Radiology, held in Chicago in September. It was not recommended for the treatment of cancer but for roentgen sickness which occurs after patients have been treated with x-rays whether they have cancers or benign tumors. In animals with freshly inoculated tumors some inhibiting effect was noticed on the tumor, but not after the growth had been well established. This is probably not due to any direct effect on

the tumor but to an impairment of the health of the animal for the injection of many substances of a toxic nature will slow down the growth of freshly inoculated tumors temporarily. No such effect was observed after the tumor was thoroughly established in the animal's body. Arons and Sokoloff combined congo red with liver extract and found that tumors also were inhibited but that the effect was only temporary. Some of the newspaper reports were slightly in error, for there was no reference in the original article to the use of congo red in the treatment of cancer.

POSTOPERATIVE MEDICATION FOLLOWING CURE OF MORPHINE ADDICTION

To the Editor—A morphine addict has been thoroughly cured for about a year. She is to have an operation July 1. After the operation morphine will have to be given to relieve the postoperative pain. Do you believe that she will become an addict again? M D Ohio

ANSWER—There is little danger of using morphine in this case, provided its administration is properly controlled. The question may be raised whether the postoperative use of morphine is mandatory in this or any other case, as there are many excellent surgeons who do not employ it for this purpose and whose patients seem to get along satisfactorily with the use, if required, of some analgesics such as acetylsalicylic acid, aminopyrine, phenobarbital and codeine, either alone or in combination. If the patient cannot retain analgesic medication, the administration of the following suppository might be advisable:

R Soluble phenobarbital	10 Gm
Aminopyrine	30 Gm
Oil of theobroma	200 Cm

Divide into ten suppositories One every four hours as required

RESPONSE OF PARALYZED PUPIL TO PILOCARPINE

To the Editor—Will a paralyzed pupil contract in response to pilocarpine? M D South Carolina

ANSWER—A pupil paralyzed by injury to the nerves of the iris will usually contract on administration of pilocarpine. The contraction lasts but a relatively short time however, and is followed by a return of the mydriasis. A pupil paralyzed by rupture of the sphincter, which can sometimes be seen only with the slit lamp, will contract but partially or not at all with pilocarpine.

POSITIVE WASSERMANN TEST IN UNRESOLVED PNEUMONIA

To the Editor—In Queries and Minor Notes in THE JOURNAL October 16 page 1300 Dr J F Loeble refers to unresolved pneumonia (x-ray diagnosis) with positive syphilitic serologic reaction. The answer given in THE JOURNAL is not quite in keeping with the facts. For some years in my ward at the Philadelphia General Hospital where the service is very large and the incidence of syphilis above the average we have frequently encountered unresolved pneumonia in syphilitic patients. My son Dr Harold F Robertson and I reported a series of cases in *Inter-national Clinics* 3 23 (Sept.) 1932. At the recent meeting of the Pennsylvania State Medical Society held in Philadelphia Dr Harold F Robertson presented a similar series before the Section on Medicine which I had the privilege of discussing at some length. This will be published in the *Pennsylvania Medical Journal*. From opportunities given to study such cases post mortem we are of the opinion that damage to the lung precedes the development of pneumonia. This is revealed by perivascular infiltrations and fibrosis of various grades necessarily dependent on the time factor of the underlying disease. We are convinced that a frank pneumonia in the absence of syphilis cannot produce a positive Wassermann or Kahn reaction. Syphilis is so all embracing in its assaults on human tissue that no legitimate reason exists which justifies exclusion of the lungs when syphilis has been present. Irrespective of its attack on nervous, bony or other structures there is always more or less cardiovascular involvement and when it is of long standing the aorta is increased in diameter to a greater extent than that seen in the hypertensive without syphilis. This of course we utilize only as a factor in determining in a relative way the duration of the syphilitic infection. In our experience syphilis existent for any length of time is definitely capable of inducing delayed resolution in lobar pneumonia. We also encounter cases of another type in which an apparent syphilitic pneumonia exists when blood cultures and all attempts at typing are negative and the physical signs are those of a lobar pneumonia though the patient is not toxic or cyanotic. One lobe or the entire lung may be involved and under antisyphilitic treatment the apical portions clear up more promptly than the base and the base may remain permanently damaged fibrotic and more or less thickening of the pleura eventuating. The third type is the gummatous lesion which is usually diagnosed as tumor by x-ray examination and which always terminates with carrying and pleural involvement. One such gumma was located in the apex of the right lung as to give rise to the diagnosis of a suppurative tumor although Horner's syndrome was absent. When resolution occurs it is very gradual and the lower lobe not seldom remains permanently damaged.

Book Notices

The Endocrines in Obstetrics and Gynecology By Raphael Kurzrok
Ph.D. M.D. Associate in Obstetrics and Gynecology the College of
Physicians and Surgeons Columbia University Cloth Price \$7.50
Pp 488 with 178 illustrations Baltimore Williams & Wilkins Com-
pany 1937

This book, by a well known investigator who has contributed original and valuable studies to clinical endocrinology, is divided into two parts of unequal merit. Approximately half is devoted to the physiology and chemistry of endocrine substances and the remainder to clinical applications and special clinical phenomena. The former shows unmistakable evidences of haste and carelessness in compilation of data, writing and proof-reading, the latter is much more adequately written and reflects a mature and critical analysis of clinical problems.

Only a few deficiencies need be selected for detailed consideration. The author uses several systems of nomenclature for a single group of substances and different spellings of the same terms interchangeably. Occasionally some designations are used incorrectly. Estrin, estrone and folliculin are used synonymously. Estrone, a specific crystalline compound, ketohydroxy estratriene, is repeatedly used in the text as a generic term for estrogens in general. "Oestrogenic" and "estrogenic" appear in successive sentences. "Estrin" often becomes "oestrin". The reader is told that estrone is "found in the ovaries, blood and excreta of all vertebrates," in "protozoa, coelenterates, worms, anthropodes [arthropods?], seeds, potatoes, female willow catkins, lignite, petroleum." Actually estrone (theelin) has been isolated and identified only in the urine of pregnant women and in that of mares and stallions. Estrogenic substances are widely distributed in nature, but these have not all been identified as estrone. In fact it is doubtful whether some of them are even closely related to estrone.

The author states "It is well known in chemotherapy that an alcohol is more active than a ketone," a thesis of dubious general validity. Even the example cited, the greater estrogenic activity of estradiol as compared with estrone, is of only limited significance as this greater potency holds only for certain species such as the rat. The name suggested by Hisaw for the progestational principle of the corpus luteum is stated to be "relaxin". The latter is a term proposed by the aforementioned worker for another substance in the corpus luteum that relaxes the pelvic ligaments in certain species of animals (as indeed the author himself recognizes in a subsequent section). Hisaw coined the name "corporin" for the progestational factor.

Typographic errors abound. The most common appears to be the interchangeable use of an amusingly large triangle and the Greek letter Δ (used in chemistry to represent double bonds) in the formulas for the steroids. In addition, author and typog-

rapher were apparently unable to decide whether the number, indicating the locations of the double bonds should be superior or inferior or in large type on the line.

In the section on the corpus luteum one finds no mention of the work of Leo Loeb. In that on the isolation of epinephrine, the name of John J. Abel does not occur. The investigations of Hanson on the parathyroid are similarly omitted.

It is disconcerting to find a statement that "the gonadotropic hormones are found only in the adenohypophysis, and in no other gland of internal secretion," and in a subsequent section a contradictory admission of the well known fact that the placenta (also an organ of internal secretion) is rich in gonadotropic substance.

Despite such errors as these, which it is hoped the author will correct in subsequent editions, the part of the book devoted to clinical problems (such as physiologic reactions of the human uterus, the alleged safety of the "safe period," menstrual disturbances and sterility) should be useful to those who treat gynecologic disturbances. The text contains numerous illustrations, excellently reproduced.

L'anaphylaxie Expérimentale et humaine Par Pasteur Vallery Radot
G. Mauric et Mme Holtzer (ex-Hugo) Paper Price 36 francs Pp
130 with 25 illustrations Paris Masson & Cie 1937

This short monograph is a summary of the work on anaphylaxis by Pasteur Vallery-Radot and his associates since 1929. The five pages of references are exclusively of the latter author. The work, of an experimental and clinical nature, embodies some of the well known facts in anaphylaxis and allergy. Briefly stated, anaphylaxis in animals (rabbits used) is always induced and is characterized by clinical shock, prolonged fall in blood pressure, vasoconstriction (peripheral and mesenteric vessels) and a decreased coagulability of the blood. In man, induced anaphylaxis is rare (as after therapeutic administration of horse serum). However, the author classifies the various allergic manifestations in man as spontaneous anaphylaxis, notwithstanding the fact that the criteria given for anaphylaxis in animals are never seen in the allergic states of man. He recommends intradermal skin tests or the Prausnitz-Kustner reaction in the diagnosis of allergic states and has found clinically that daily intradermal injections of cutaneous test doses over periods of months is of greater value in desensitization than weekly or biweekly intradermal or subcutaneous injections. He does not believe that a true desensitization is ever accomplished in man. The monograph will appeal more to those interested in the experimental phase of allergy than to those engaged in its clinical application.

Emanotherapy By F. Howard Humphris M.D. F.R.C.P. D.M.R.F.
Honorary Consulting Radiologist to and Member of the Medical Advisory
Board of St. John Clinic and Institute of Physical Medicine London
and Leonard Williams M.D. Cloth Price \$3 Pp 188 with 6 illus-
trations Baltimore William Wood & Company 1937

The term emanotherapy is used here to include the treatment of widely differing pathologic conditions, except malignant conditions, with small amounts of radon in such forms as drinking water, baths and muds. This form of treatment is here referred to as emanotherapy in order to differentiate it from treatment in which radium salt is used. The author definitely emphasizes the fact that he refers only to treatment with radium emanation and never to treatment with radium salts. Furthermore, nothing in this book concerns itself with the application of radon in concentrated form, as it is used for local treatment of malignant diseases. Therefore, all objections which arise from the knowledge of the danger of repeated administration of radioactive salts are at once eliminated. The scope of the book is limited to the use of small amounts of radon in the different types of treatment already mentioned.

Since radon has a short life span, all preparations of this type deteriorate with relative rapidity. The gas is eliminated quickly, particularly through the lungs. The blood has only a certain power of absorption of this gas and the excess is also rapidly eliminated here. The danger of accumulation, therefore, which is always present in treatment with radium salts, is absent in all types of treatment with radon.

After an introductory chapter giving the history of emanotherapy, the scientific literature on the effect of such treatment

is surveyed. In two chapters on technical considerations the different procedures for the administration of this treatment are discussed: treatment by inhalation, by ingestion of radioactive water, by cutaneous application with pads and compresses as well as with creams and pomades and radioactive baths and muds; subcutaneous injection, insufflation into the rectum and the vaginal douche.

In the following chapter the clinical indications for the various clinical specialties are considered: gout and rheumatism, gynecology, otorhinology and dermatology. In a special chapter the treatment with muds is discussed, particularly from the point of view of whether the radiating energy is the most effective factor in this type of treatment. The authors answer this question in the affirmative. Some less common indications for the use of emanotherapy are discussed extensively in a separate chapter.

The book has been written with the purpose of spreading the knowledge of the clinical application of emanotherapy in Great Britain, where, in contradistinction to many countries and particularly those on the European continent, this treatment is not very popular. From this point of view the book is a convenient guide. However, one might wish for a more critical survey of the subject. It should be remembered that certain of the natural spas known for their curative effects in certain pathologic conditions have an emanation content below the threshold of physiologic efficiency. Yet it has been the experience of some of the most prominent clinicians that the use of these waters is considerably more effective than treatment with artificial radioactive substances or solutions, even though these artificial agents may contain a much higher amount of radioactive material. Therefore, while the radioactivity may have a certain part in the action of these therapeutic agents, there are certainly many other effects encountered in these results which may be explained by other factors, such as temperature. When one considers the beneficial effects of mud compresses, which contain only infinitesimal amounts of radioactivity, there is a great question as to whether such beneficial effects are due to the radioactive materials or to some other factor.

This book fills a definite gap in that it gives a convenient source of information covering the whole field dealing with this type of treatment, with competent explanations of the physical and biologic problems involved.

A bibliography is appended to each chapter.

The Control of Tuberculosis in England Past and Present. By G. Gregory Kayne, M.D., M.R.C.P., D.P.H., Deputy Medical Superintendent, County Sanatorium, Clare Hall, Middlesex. With foreword by Sir Humphry Rolleston, Bart. G.C.V.O., K.C.B. Cloth. Price \$3. Pp. 188. New York & London: Oxford University Press, 1937.

This book deals with the whole problem of tuberculosis control in England. The first part includes treatment and prevention before 1908. While the cause of the disease was known, this was before the present method of administering the tuberculin test intracutaneously was employed. Moreover, artificial pneumothorax was not used in England at that time. The hospital and sanatorium situation prior to 1908 is presented in considerable detail, as well as the high mortality from the disease. In the second part such subjects as reporting of cases of tuberculosis and various acts, such as the National Insurance Act and the Local Government Act are presented. One chapter is devoted to control of tuberculosis before the Great War, another to control during the war, and a third to progress in control since the Great War. Part III contains an excellent discussion of the present day tuberculosis problem in England. Tables are presented showing the decrease in mortality. The author presents a most modern point of view with reference to control of tuberculosis among children by emphasizing the importance of protecting them against communicable cases of the disease. He calls attention to the fact that the bovine type of tubercle bacillus as a cause of pulmonary tuberculosis is not so rare as was formerly believed, in fact, in children he estimates that 25 per cent of the deaths from all forms of tuberculosis can be attributed to the bovine type of tubercle bacillus. Such facts should cause every physician in the United States to appreciate more than ever before the value of the work of veterinarians in controlling tuberculosis among cattle. The author believes that every attempt should be made to prevent

tubercle bacilli of both human and bovine types from entering the bodies of children as long as possible. He calls attention to the fact that many persons now reach adult life without tuberculous infection and that every effort should be put forth to protect adults against exposure. The importance of the intracutaneous tuberculin test is emphasized for both children and adults. He thoroughly appreciates the value of the x-ray film in locating areas of disease and determining more accurately their extent than can be done by any other method. With reference to the detection of activity of the tuberculous lesion, he says "Radiology has not reached the stage at which the degree of activity of the lesion may be judged with any degree of accuracy, but it has demonstrated the existence of latent lesions which may recrudescence."

In the section on treatment, collapse therapy is given an important place. Although there exists in England a difference of opinion as to whether artificial pneumothorax should be instituted in the absence of pulmonary cavities, the author states that, since artificial pneumothorax may lead to considerable shortening of institutional treatment, enables patients to carry on with their work while under treatment and is the most rapid method of rendering a patient noncontagious, he definitely appears to favor its adoption even in the noncavernous cases in the working classes. In the prevention of tuberculosis, the chief emphasis is placed on finding, treating or isolating persons with tuberculosis in communicable form. Considerable emphasis is placed on open-air schools, preventoria and special buildings on sanatorium grounds for infected children. This is contrary to the present trend in the United States, where such institutions for children who do not have clinical disease are being abolished. It is gratifying to see emphasis placed on the role of the general practitioner in the tuberculosis control program. This book contains much valuable information and should be available to all physicians engaged in any phase of tuberculosis work.

Modern Psychology in Practice. By W. Lindesay Neustatter, B.Sc., M.B., B.S., Clinical Research Assistant to the Dept. of Psychological Medicine, Guy's Hospital. With a foreword by R. D. Gillespie, M.D., F.R.C.P., D.P.M., Physician in Psychological Medicine, Guy's Hospital. Cloth. Price \$3.75. Pp. 299. Philadelphia: P. Blakiston's Son & Co., Inc., 1937.

This book, by a London psychiatrist, is an introduction to the psychology of the commoner mental disorders. A brief introduction to general psychopathology is followed by an even briefer rapid review of the chief concepts used by the several "schools of thought," such as the Freudian and the Adlerian. Children's disorders are presented from a pediatric rather than a psychiatric point of view. Here a wide field is sketchily outlined, the discussion including problems of anxiety in children, behavior problems, speech disorder, mental defect and methods of treatment. The commoner neurotic disorders and psychoses among adults are discussed. A section on methods of treatment gives the author's personal experience in treatment approaches, based primarily on psychoanalysis. A concluding general section on psychology and general medicine discusses psychologic aspects of asthma, rheumatism, cardiac disturbances and other common conditions. Causation and prophylaxis curiously are treated at the end of the book. The volume should be useful to physicians and medical students who wish to acquaint themselves with current thinking in the field of medical psychology and psychotherapeutics. The author, a physician at Guy's hospital, was formerly a Commonwealth fellow in child psychiatry and is well oriented in his field. The book is written frankly as representing the author's own reaction to current teaching and reflects his own clinical experience. Necessarily much of the discussion is too fragmentary and sketchy to be of great use to the physician who wishes to prepare himself for actual clinical work with mentally disturbed patients, but the book should be of great value to the general practitioner in aiding him to a helpful approach to such patients in the course of general practice. The author's special emphases in treatment approaches appear to be unduly colored by stekelian influence. Specialists in the various schools of psychotherapeutics will differ with the author in many details but will recognize the validity and general soundness of his treatment approaches. The book is much more readable, much more understandable and much more authentic than most books on medical psychology written for

laymen and medical students. A felicitous style, clear language and a ready wit, rare in medical writings, enliven the book and give one the impression that, whatever the merits or deficiencies of the author's particular views, doubtless he is an excellent psychotherapist and is willing to tell how he does it and what he thinks about his work. Medical students should read this book.

Das Serum Eisen und die Eisenmangelkrankheit (Pathogenese, Symptomatologie und Therapie) Von Ludwig Hellmeyer, Oberarzt der Medizin. Uniklinik Jena und Kurt Plotner, Assistenzarzt der Klinik. Paper. Price 6 marks. Pp. 92 with 22 illustrations. Jena: Gustav Fischer, 1937.

The determination of serum iron has always presented technical difficulties which have been an obstacle to the thorough study of the iron deficiency state. This monograph concerns itself with not only the pathogenesis, symptomatology and treatment of conditions associated with iron deficiencies but also with methods for iron determination. The authors give a detailed description of their method in the first part of their monograph. The values for a small group of normal men and women are given and no direct relationship was found between the hemoglobin content of their blood and serum iron. Following the discussion on technique are clinical observations on acute and chronic posthemorrhagic anemias, primary hypochromic anemia, hemolytic anemia, leukemia, polycythemia vera and postinfectious anemias. The serum iron in tuberculosis and rheumatic fever is next discussed. The authors then discuss the metabolism of iron in normal and pathologic states. Treatment of the iron deficiency states conclude the monograph. The text is frequently illustrated by graphs and charts but the bibliography is glaringly deficient in pertinent references. While the material presented by the authors is a contribution to the work in this field, it is by no means of monographic scope. Furthermore, the author's clinical observations are inadequately controlled.

Physical Aspects of Radium and Radon Therapy By Dr. C. E. Eddy, F. Inst. P., Physicist in charge and Mr. T. H. Oddle, M.Sc., A. Inst. P., Physicist of the Commonwealth X-Ray and Radium Laboratory, University of Melbourne, Commonwealth of Australia. Department of Health. Paper. Pp. 60 with 14 illustrations. Canberra: F. C. T. [n. d.]

This useful pamphlet has been prepared by several Australian physicists and is distributed by the government to those working with radium. It contains a clear summary of the most important phases of our knowledge of the physics of radium, of the methods of placing radium and radon in the containers, size and construction of these containers, tables of the decay of radon, a discussion of the advantages and disadvantages of radon as compared to radium, and of the conditions governing the issuance of government radium to hospitals, approved medical practitioners and research workers. The Australian Department of Health owns 10 Gm. of radium and the report suggests that where radium is to be distributed it is best used in the form of radon. No instructions are given for the clinical application of these two forms of radiation.

Chronic Miliary Tuberculosis By Clifford Hoyle, M.D., M.R.C.P., Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton, and Michael Valzey, M.B., M.R.C.P., Medical First Assistant and Registrar, London Hospital. Cloth. Price \$4.25. Pp. 140 with 18 illustrations. New York & London: Oxford University Press, 1937.

In this book the authors present 110 cases of chronic miliary tuberculosis selected from the literature and ten additional cases which they are reporting for the first time. All 120 patients lived three months or more after the disease was recognized. Attention is called to Waller's statement in 1845 to the effect that persons suffering from miliary tuberculosis might recover and also to examples which Wunderlich presented in 1860. Since that time numerous cases have been reported but in many the evidence was not found to be sufficient to justify their inclusion in this monograph. The authors present their personal series of ten cases in considerable detail with reference to clinical manifestations, x-ray and laboratory observations and morbid anatomy. Under treatment they state that the disease may heal completely and the patient may remain well. They believe that formerly such patients were given prolonged and unnecessary hospital or sanatorium treatment on the basis of persistent shadows on the x-ray film. They describe another

group of cases in which the disease advances steadily and is not unlike acute miliary tuberculosis except that the patients live a little longer. For this group treatment is of no avail except that which brings about relief from symptoms. For the intermediate group they recommend rest and suggest partial bilateral artificial pneumothorax, although this has not been attempted. However, in one case in which the miliary tuberculosis was unilateral they did institute artificial pneumothorax. Two patients who were treated with sanocrysin recovered, while three others did not respond, three patients treated with tuberculin showed no improvement. Various other methods of treatment, such as heliotherapy and splenectomy, are discussed. This monograph contains a good presentation of the subject, with a list of 217 references, seven tables, and eighteen illustrations made from x-ray films of the chest and pathologic specimens.

A Text Book of Medical Bacteriology By R. W. Fairbrother, D.Sc., M.D., M.R.C.P., Lecturer in Bacteriology, University of Manchester. Cloth. Price \$4.50. Pp. 437 with 17 illustrations. St. Louis: C. V. Mosby Company, 1937.

The author states that this book is an outline of the medical aspects of bacteriology. With this aim it of necessity straddles the two fields and is unable therefore to do complete justice to either bacteriology or medicine. As an example of its partial inadequacy from a bacteriologic standpoint is the omission of any description of the Barber single cell method of isolating bacteria in the discussion of pure cultures. Certain advantages, however, are evident. Chemotherapy with sulfamidamide for streptococcal infections is mentioned briefly but is already out of date. With the admirable brevity often characterizing the English textbooks, the author has been able to discuss general bacteriology from the standpoints of biology, infection, immunity and so on, systematic bacteriology including the more important bacterial diseases, filtrable virus, bacteriophage and the bacteriology of water, milk and shellfish. Finally there are three chapters on technique which might well be placed perhaps in a laboratory manual rather than in a textbook of this sort. In an attempt to simplify the reading matter, the author has not cited specific references in the body of his material, the end of the chapters, or the general index. This is an omission which will make the book practically useless as a starting point for more detailed investigation of various subjects. Furthermore the index is brief and could well be expanded in future editions.

Manual of the Diseases of the Eye for Students and General Practitioners By Charles H. May, M.D., Consulting Ophthalmologist to Bellevue Mt. Sinai and French Hospitals, New York. Fifteenth edition, revised with the assistance of Charles A. Perera, M.D., Instructor in Ophthalmology, College of Physicians and Surgeons, Medical Department of Columbia University, New York. Cloth. Price \$4. Pp. 498 with 376 illustrations. Baltimore: William Wood & Company, 1937.

The standard nature of this textbook is readily apparent from the fact that this is the fifteenth edition since 1900 and that there are British, Spanish, French, Italian, Dutch, German, Japanese and Chinese editions as well. The last previous American edition appeared in August 1934 and was reprinted in August 1936. The author states in the preface that the chapters on the ophthalmoscope and the ocular manifestations of general diseases have been rewritten and that much new information has been included on the subjects of operations on the lids and the retina. Obsolete matter has been deleted, with the highly desirable result that in spite of the advances in knowledge in this field there has been little increase in the size of the book. This edition remains an excellent introductory textbook for medical students and a source of convenient reference for the physicians who are not specializing in diseases of the eyes.

Chemie der Inkrete und ihre wichtigsten Darstellungsmethoden Von Dr. Kurt Maurer, a. o. Professor für Chemie an der Univ. Jena. Band I: Zwinglose Abhandlungen aus dem Gebiete der Innere Sekretion. Herausgegeben von Professor Dr. W. Berblinger. Paper. Price 7.00 marks. Pp. 67. Leipzig: Johann Ambrosius Barth, 1937.

This is a brief dissertation on the chemistry of estrogens and androgens, progesterone and related steroids, insulin, epinephrine, adrenal cortical principles, thyroxine, hypophyseal and parathyroid principles and the so-called circulatory hormone occurring in the pancreas and the urine. Those who desire a bird's eye view of the subject will find this treatise useful.

Report of the Advisory Council Science Museum Board of Education
for the Year 1936 Paper Price 1s 3d Pp 51 with 6 Illustrations
London His Majesty's Stationery Office 1937

The Science Museum of London does not include medicine or the medical sciences as a unit. Since many physicians are interested in the basic sciences, however, there is much of interest to him in the museum. Among the new exhibits listed for 1936 might be mentioned those on smoke abatement and sewage disposal.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Pharmacists Liability for Injuries Attributed to Preparation Sold as a Wart Remover—The plaintiff sued the defendant drug company, attributing certain injuries he sustained to the use of a preparation sold him by an employee of the company as a wart remover. The trial court gave judgment against the plaintiff and he appealed to the court of appeals of Georgia, division 1.

The preparation purchased by the plaintiff was in a bottle and the directions pasted thereon advised the purchaser to apply the lotion to the affected parts four times a day. The plaintiff alleged that he carried out these directions and applied the preparation to his wart four times daily for about ten days, that soon after he began using it the wart turned black, and his hand began to swell and became inflamed and infected, causing him great physical pain and mental anguish. Finally, it was alleged, a skin cancer developed. These results, it was contended, were caused "proximately and solely by the said preparation sold to him by the said defendant," being due to some harmful and dangerous ingredient contained in the preparation. When the case came to trial, however, the plaintiff failed to prove that the preparation sold to him contained a harmful and dangerous ingredient. The trial court, therefore, properly granted a nonsuit and the court of appeals. If the allegations that the preparation contained a harmful and dangerous ingredient were true, that fact could have been sustained by proof of a chemical analysis of it. In the absence of any such proof, the plaintiff failed to substantiate his allegations. The judgment for the defendant was affirmed.—*Brewer v Knight Drug Co, Inc (Ga)*, 190 S E 365.

Workmen's Compensation Acts Cerebral Hemorrhage and Ensuing Paralysis Attributed to Excitement—The claimant, a Negro 50 years old, but a man while driving a truck in the course of his employment. He became highly nervous and excited slumped over the steering wheel and was taken from the truck to a hospital, paralyzed in his right side. For the ensuing disability, he sought compensation under the workmen's compensation act of Maryland. The industrial commission denied him compensation, the Baltimore city court reversed the commission's finding and the employer appealed to the Court of Appeals of Maryland.

The physical condition of the claimant before the accident was not good. According to the testimony of expert witnesses who testified for him he had an excessive blood pressure and a premature hardening of the arteries. If he had suffered a paralysis while napping or while uneventfully driving his truck in the course of his employment the paralysis occurring would have been a natural and probable result of his impaired physical health and would have possessed none of the essentials of an accidental happening. The disease, or malady, however, did not run its natural and anticipated course. The claimant was precipitated into paralysis as the result of an accident. The sudden and unexpected action of a man riding a truck ahead of the claimant made it necessary for the claimant quickly to turn his truck in an effort to avoid striking him. Between the beginning of his excitement when the man jumped into the way of his truck and the shock of the truck's collision with the man's body the paralysis happened. So far as the claimant is concerned the court said all the elements of unin-

tention, unexpectedness, and happening by chance, concur in making the occurrence an accident. In the opinion of the court, there was no fundamental difference in law or in principle between an injury causatively resulting from a blood vessel being cut or crushed and one ruptured by an artificial distention of that blood vessel from fright, apprehension or exertion directly and proximately a consequence of an accidental event.

If an employee, while at work, suffers or is made ill from natural causes, the condition is not accidental since it is a natural result or consequence which is normal and to be expected. If, however, there is a subsisting illness or disability which is caused or accelerated by some act or event coming by chance or happening fortuitously, then the resulting condition is considered as having been caused by an accident. It is not necessary for the accidental quality or condition to be given or created by a wound or by external violence.

The court concluded, therefore, that the claimant had suffered an accidental injury arising out of and in the course of his employment. The judgment of the lower court in effect awarding compensation to the claimant was affirmed.—*Geipe Inc v Collett (Md)* 190 A 836.

Workmen's Compensation Acts Implied Consent of Employer to Physician Selected by Employee—The Oklahoma workmen's compensation act requires an employer to provide promptly for an injured employee such medical and other treatment and care as may be necessary during sixty days after the injury or for a longer period if necessary in the judgment of the commission. If the employer fails or neglects to provide such treatment within a reasonable time after knowledge of the injury, the injured employee, during the period of such neglect, or failure, may procure the necessary treatment at the expense of the employer.

Under this statute, said the Supreme Court of Oklahoma in *Oklahoma Utilities Co v Johnson*, 66 P (2d) 10, it is not necessary, in order to render an employer liable therefor, for the employee to request the employer to furnish medical aid, if the employer has notice of the injury and the necessity for medical attention. If the employer has knowledge of the fact that the employee has retained his own physician and responsible officials of the employer visit the employee without making any objection to the physician selected or suggesting some other one, the employer will be deemed to have impliedly consented to the arrangements made for the necessary medical attention.

A somewhat similar holding was reached by the Supreme Court of Oklahoma in *United States Casualty Company v Steiger* 66 P (2d) 55. There the court said that an employer should be given an opportunity after having knowledge of the injury to furnish the medical attention and select his own physician and where he has done so the employee should accept such service. But if the employer knows that an employee has selected his own physician and does nothing toward providing a physician of his own choice or indicating a dissatisfaction in the choice of the employee, he will be deemed to have consented to such selection as though the physician were selected by the employer.—*Oklahoma Utilities Co v Johnson (Okla)* 66 P (2d) 10 *United States Casualty Co v Steiger (Okla)* 66 P (2d) 55.

Health Insurance "Totally Disabled" Defined, Admissibility of Medical Expert Testimony—Forrester and Ranev as members of the Brotherhood of Locomotive Firemen and Enginemen, had received benefits prior to 1933 for total disabilities caused by tuberculosis. In 1931 the Brotherhood amended its constitution so as to define total and permanent disability as a state of bodily incapacity as shall wholly and permanently prevent a member from engaging in any occupation, profession or business or from performing or directing any work for remuneration or profit. In 1933 the brotherhood refused to pay further benefits on the ground that Forrester and Ranev were no longer totally and permanently disabled within the meaning of the new constitution even though in the opinion of physicians they had tuberculosis in the active stage and were unable to perform physical labor without endangering their health and lives. Forrester and Ranev later instituted separate suits against the brother-

hood to recover additional benefits. From judgments in favor of the plaintiffs, the brotherhood appealed to the court of civil appeals of Texas, Austin.

In the opinion of the court of civil appeals, the trial courts had not erred in giving the following instructions:

totally disabled does not imply an absolute impossibility to perform any work. A person is totally disabled when his physical condition is such that he is unable to perform or direct any work without injury to his health, and when common prudence and the exercise of ordinary care would require him to desist from the performance of his duties.

An insurer, said the court, has the right to place such reasonable restrictions and conditions on its liabilities as it may see fit. However, when it attempts to define such limits by using relative terms whose meaning cannot be prescribed with factual exactitude, such terms must be given the meaning and interpretation placed on them in the adjudicated court decisions.

On appeal of the suit instituted by Raney, the court set forth certain cardinal principles relative to the admissibility of medical expert testimony. Statements, said the court, made by a patient to his physician as to subjective symptoms for the purpose of qualifying such physician to testify, and not for purposes of treatment, are inadmissible in evidence, and testimony as to a diagnosis based on such statements or medical history is likewise inadmissible. However, the testimony of a physician as to a diagnosis made by him from objective symptoms and from his own examination of the patient, independent of what the patient may have told him, is not inadmissible even though the patient may have made self-serving declarations to him.

Accordingly, the court of civil appeals held that the plaintiffs were totally and permanently disabled and affirmed the judgments in their favor—*Brotherhood of Locomotive Firemen and Enginemen v Forrester (Texas)* 101 S. IV (2d) 860, *Brotherhood of Locomotive Firemen and Enginemen v Raney (Texas)*, 101 S. IV (2d) 863.

Harrison Narcotic Act Administration of Narcotics as Constituting a Sale, Entrapment of Physician—Ratigan was convicted in the district court of the United States for the western district of Washington, northern division, for selling morphine by means of hypodermic administration, and not in pursuance of an order on a form issued by the Commissioner of Internal Revenue. *United States v Ratigan* 7 F. Supp. 491 abstr. THE JOURNAL, May 4, 1935, page 1665. He thereupon appealed to the United States circuit court of appeals, ninth circuit.

The indictment under which Ratigan was convicted charged that he "did feloniously sell morphine by means of hypodermic administration not in the course of the professional practice or in good faith, or for legitimate medical purposes merely for the purpose of gratifying his (purchaser's) craving for the drug not in pursuance of a written order on a form issued in blank for that purpose by the Commissioner of Internal Revenue." Ratigan first contended that the indictment did not charge an offense under the law. With this contention the circuit court of appeals disagreed. The essence of "sale" is, the court said, a transfer of the property in a thing for money. That the narcotics administered by Ratigan constituted property may not be questioned. The delivery or transfer of the narcotics by Ratigan hypodermically to the buyer and payment for this hypodermic injection were not challenged. The transaction, therefore, had all the component parts of a sale. A sale is complete when the drug is delivered whether hypodermically into the human system by request of the buyer or delivered elsewhere on his direction. It does not need to be personally handled by the buyer. The allegation in the indictment, continued the court, that the sales were made "not in the course of the professional practice of [appellant], or in good faith, or for legitimate medical purposes, he [the purchaser] being free from any disease in which morphine is indicated for legitimate medical purposes, and receiving same, as aforesaid, from [appellant] merely for the purpose of gratifying his craving for the drug," sufficiently negated the exception contained in the Harrison Narcotic Act providing that nothing contained in it should apply to the dispensing to a patient by a physician in the course of his professional practice only.

There was no entrapment in the case, in the opinion of the court. Ratigan was not led into a situation where he committed the act innocently. The stool pigeons merely presented themselves to Ratigan and solicited the drug; there was no decoy solicitation or conduct. What Ratigan did was his free, voluntary act, the stool pigeons affording the opportunity for the sale of the drug. The defendant admitted administering from eighty-eight to 100 treatments daily, averaging approximately 4 grains, more or less, each, and that he purchased, during 1935, 194,000 one-half grains, or 97,000 grains of the drug. The evidence indicated, the court said, that Ratigan administered 29,720 grains not purchased on order blanks. The judgment of conviction was therefore affirmed—*Ratigan v United States* 88 F. (2d) 919.

Accident Insurance "Total and Permanent Disability" Defined—The defendant insurance company promised to pay certain benefits to the plaintiff if he sustained an accidental injury that would "wholly and continuously disable the insured from transacting any and every kind of business pertaining to any occupation." As the result of an automobile accident the plaintiff lost the use of his right hand and arm and was thereafter unable to perform the manual duties connected with his customary occupation as a distributor of beer by truck. He did, however, continue his business by employing and supervising help and was thus able to prosper. He later sued the defendant insurance company, claiming that he had become totally and permanently disabled. From a judgment in his favor, the insurance company appealed to the Supreme Court of Arkansas.

Clauses similar to the one in the insurance policy in question said the Supreme Court, have been construed by this court to mean that an insured is totally and permanently disabled when the injuries received prevent him from performing or executing all the substantial and material acts of his business in the usual and customary way. In the opinion of the court the jury was warranted in finding from the evidence that the plaintiff had become totally and permanently disabled within the meaning of the clause in question. He was no longer able to drive his truck and load and unload the same in person which were material and substantial acts in conducting the business of distributing beer. The court also pointed out that as a result of his injury he was no longer able to perform the duties necessary in the operation of a steam shovel, repairing automobiles and doing carpenter work, which were the only other occupations he had been trained to follow.

Accordingly, the Supreme Court affirmed the judgment in favor of the plaintiff—*Monarch Life Ins. Co. v Riddle (Ark.)*, 101 S. IV (2d) 781.

Hospitals Liability of Charitable Hospital for Injury to Pay Patient—A pay patient in a hospital, said the court of appeals of Georgia, division 2, classified and operated primarily as a charitable institution, who is injured through the negligence of the hospital, may recover damages from the hospital for such injuries although the recovery will be restricted to the income derived from pay patients or other noncharitable sources—*Robertson v Executive Committee of Baptist Convention (Ga.)* 190 S. E. 432.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

*Simple Cysts of the Ovary Their Clinical Importance E V Stabler, Greenville —p 150
The Dietitian Anna M Tracy Tallahassee Fla —p 155
Paget's Disease (Osteitis Deformans) M Barfield Carter Birmingham —p 157
The Old School and the New S Graves University —p 163

Simple Cysts of the Ovary—Stabler selected ninety-three patients for his discussion because their symptoms seemed to relate directly to the ovary, both preoperatively and postoperatively. Follicular, luteum and retention cysts were generally the rule. All the patients had cystic ovaries that were diagnosed at the time of operation. Two symptoms were common to all cases, a boring type of pain in one or both sides, and an increase of pain at menstruation, of a bearing down type. Fifty-five patients had pain in the back, fifty-three had pain down the leg, fifty-eight had regular menstruation, twenty-three had irregular menstruation and thirty-seven had to go to bed because of pain at the menstrual period. His treatment was the resection of the ovary, removing all cystic tissue if as much as one sixth of the ovarian tissue could be left, removal of the entire ovary if the whole ovary was cystic, puncture of the cysts when only a few cysts were found. In all patients, when it was deemed advisable, who were more than 36 years of age, the entire ovary was removed if it was cystic, both ovaries if both ovaries were cystic. Postoperative results, which range from six years to four months show freedom from pain in forty-seven cases, pain after operation that corresponded to the resected ovary in thirty-two cases, pain after operation that corresponded to the removed ovary in fifteen cases and pain after operation believed to be due directly to the remaining ovarian tissue in twenty-three cases. The regularity of menstruation improved in thirty-three cases, menstruation was unimproved in seventeen cases, the menstrual cycle was shorter and the flow more moderate in sixty cases, forty-one patients were apparently improved and five were apparently unimproved. Recognition of or the failure to recognize, the clinical importance of multiple follicular, luteum or retention cysts of the ovary may result in the success or failure of a major surgical procedure as far as the clinical results to the patient are concerned.

Pathologic Basis for Intermittent Claudication—Neal presents an analysis of the vascular changes as demonstrated by arteriography in forty-one cases in which intermittent claudication was the predominant symptom and in all of which the basic vascular pathologic change was arteriosclerosis. In most cases other signs and symptoms of vascular degeneration were present in addition to the pain due to exercise and in

eight cases gangrene of one or more toes was also exhibited. There was a wide variation in the duration and severity of the pain due to exercise. In twenty-one cases there was complete femoral or popliteal (or both) obstruction at some part of one of the large trunks. In six cases there was a definite, marked narrowing of the lower femoral and the popliteal arteries, although in no instance was the obstruction complete. The collateral circulation in these cases varied considerably. In all the cases in which one or more of the large trunks was completely obstructed or markedly narrowed, there was diminution in the number of functioning muscular branches. This was particularly evident in the smaller branches, and some arteriograms showed large areas of muscle devoid of any small muscular branches. In fourteen cases the large vessels of the extremity were patent throughout their course and their lumens were within normal range. Sometimes their course was tortuous but there were no points of constriction or obstruction. Here the defect was in the small muscular branches. The single abnormality common to all these cases is the obstruction of the small muscular branches with their fine terminal twigs. The obliterative process may affect all the muscles of the extremity, or a single muscle, or even an isolated portion of some muscle. Further proof that it is the obliteration of these fine vessels which is responsible for the impairment of muscular function is supplied by repeated arteriographic studies on patients whose intermittent claudication has improved under treatment, in which there is an increase in the number and size of the fine terminal arteries, as well as an improvement in their distribution. It is the abnormal distribution of the blood supply and the inaccessibility of certain portions of the muscles which produce impaired nutrition.

Hemolysis in Nephritis in Saponin Systems—Herrald and Pijoan consider the exact relationship of cell and serum components in standardized saponin systems. Their investigation proceeded along two lines: the hemolysis by saponin of washed red cells and the effect on hemolysis of serum from nephritic patients. The principle of the method they employed is that described by Ponder in which the lysis (saponin) is added quantitatively to a known volume of washed red cells in saline solution and the velocity of hemolysis noted. It was found that the serum of patients with glomerulonephritis has a marked inhibitory effect on hemolysis by saponin. The reason for this is not clear. Work is now being carried out to deter-

mine the relationships of the various lipoids and proteins in the serum to this phenomenon. It is conceivable that, if there are substances which affect the red cell membrane in any way altering their reaction to saponin, these substances may play a part in influencing red cell metabolism in disease.

Investigations on Hemophilia.—Bendien and van Creveld discuss the fact that in normal fresh plasma and serum a substance is present which exerts a coagulation-promoting influence on hemophilic plasma and blood. A method is described for precipitation of the coagulation-promoting substance from normal fresh serum by slight acidifying. A simpler method is also described, i.e., adsorption and elution, by which the coagulation-promoting substance can be obtained from fresh normal serum in a medium poor in proteins. By dissolving the coagulation globulin (which was precipitated from the serum by slight acidifying) in water or in physiologic solution of sodium chloride to which has been added 3 or 4 per cent of sodium carbonate, it can be dissolved in a volume which is ten times as small as the volume of the normal serum from which it has been prepared. The solution is free from cholesterol and lipid phosphorus. The solutions as obtained by the method described showed an activity which was about five times as great as that of the fresh serum itself. These solutions remained active much longer than the serum itself when kept in the refrigerator. Oral, intramuscular or intravenous administration of the coagulation-promoting substance has been tried in three patients with hemophilia. In one patient the coagulation time had been kept repeatedly within normal limits for some days by an intravenous injection.

Relation of Vitamin B Intake to Mental and Physical Growth.—Colby and her co-workers made psychologic observations of the mental and physical growth of artificially fed infants who lived in their own homes and were cared for by their parents. At the initial observation in the growth clinic all the babies were $2\frac{1}{2}$ months of age or less, the minimum age was 5 days and the average age $5\frac{1}{2}$ weeks. An effort was made to determine the nutritive advantage to the health, the related growth-promoting phenomena and the bone-building value of supplementary amounts of vitamin B in the form of a water extract of rice polishings. Criteria for the estimation of the nutritive advantages were looked for in monthly medical examinations, according to which an increase of from 30 to 50 per cent in the intake of vitamin B appeared to produce more regular, though not consistently greater, growth in infants, as judged by the group averages of the various measurements. Increased amounts of vitamin B in the diet seemed to promote a more stabilized growth and greater nutritional stability. The general mental picture of the infants receiving increased amounts of vitamin B may perhaps be qualitatively summarized as one of slightly accelerated maturation in basic behavior patterns (except the sympathetic), augmented alertness in attention and perception phenomena and slightly accelerated adaptive behavior patterns (learning). All available data on vitamin B seem to indicate some close interaction in the infant between the metabolism and the development of external behavior. The nature of this interaction can be shown only by further and more highly controlled observations.

Incontinence of Urine in the Female.—Kennedy believes that the external sphincter exerts little force in preventing the escape of urine from the bladder, the normal internal involuntary sphincter alone may have sufficient power to prevent the escape of urine from the bladder. When the free involuntary internal sphincter is enhanced by the normal voluntary sphincter, the control is quite positive. He outlines an operation for the restoration of sphincter control. He describes the sphincter mechanism as made up of a free involuntary sphincter surrounding the inner third of the urethra supported and enhanced by a voluntary sphincter composed of the anterior portions of the levator muscles, which unite in a median raphe beneath the urethra. The sphincter mechanism lies around and beneath the middle third, having more and stronger fibers in this location. A woman who has never had a labor but who begins to suffer a partial incontinence of urine due to loss of sphincter control may have had an incomplete union of the fibers composing the involuntary sphincter and the voluntary sphincter. Labor may injure (1) separately the involuntary sphincter by directly or indirectly causing it to be distorted and fixed to the ramus of the pubis, thereby markedly diminishing its function as a sphincter and (2) separately the voluntary sphincter by splitting its fibers parallel to the urethra in or adjacent to the median raphe and (3) conjointly at the same labor 1 and 2. O

twenty-eight patients, twenty-six have had urinary control restored, one has an incontinence which may not be permanent and one has sufficient incontinence which may require a second operation

Effect of Pregnancy on Malignant Tumors—During the last ten years Smith collected fifty-four instances in which patients with malignant tumors also had one or more pregnancies occurring either simultaneously with the appearance of the tumor or following its treatment. He reviews this series to determine whether pregnancy had a detrimental effect on the malignant tumors. He concludes that pregnancy is detrimental and should be prevented in patients having unarrested malignant tumors. Growing malignant tumors may be temporarily retarded by pregnancy, but the growth is accelerated after the termination of the pregnancy. Pregnant patients with malignant tumors have a better prognosis if (1) the pregnancy is not interrupted, (2) the pregnancy follows treatment of the tumor rather than occurs simultaneously with it, (3) in patients becoming pregnant after the tumor therapy, more rather than less than two years has elapsed since the tumor therapy, (4) in the breast and nongenital groups the patient has not aborted, regardless of the time relationship of the pregnancy to the occurrence of the tumor and (5) the breast and genital tumors are treated before the end of the pregnancy. If the patient has aborted, there is some slight advantage in early over late abortion in the nongenital group, but a distinct disadvantage in the breast group and total. All groups fared better if abortion did not occur, regardless of the stage of the pregnancy when first seen. Abortion was especially disastrous to primigravid women, whereas both primigravid and multigravid women did about equally well if abortion had not occurred. Irradiation of the breast and nongenital tumors in pregnant women has no tendency to produce malformed babies. In the genital group irradiation of the pelvic regions will usually produce abortion in the early months of pregnancy. In the latter months of pregnancy, carcinoma of the cervix can be irradiated locally without affecting the fetus or producing abortion. Of forty-one known viable normal offspring at birth, only twenty-five could be traced and these aged 1 to 10 years, show no evidence of any bad effects from tumor therapy.

Rheumatic Fever and Bacterial Endocarditis—Gross and Fried describe the changes in the hearts in forty-two cases of subacute bacterial endocarditis and twenty-eight cases of acute bacterial endocarditis. While there is no sharp line of distinction between these conditions and a variety of lesions are common to the two, certain features are of aid in classifying the bacterial endocarditis into these two categories. An important, differentiating histologic feature is the spongy lesion that occurs in its typical form, perhaps exclusively, in subacute bacterial endocarditis. About 75 per cent of the hearts of patients having bacterial endocarditis had been the seat of a previous rheumatic process. Activity of a rheumatic infection is not a necessary precursor to the development of bacterial endocarditis. Aschoff bodies were encountered in about 30 per cent of the superimposed cases of acute and subacute bacterial endocarditis. Some of these cases were thrown into activity

by the superimposed bacterial infection, rather than the activity of the rheumatic process predisposing to the bacterial endocarditis. Certain mechanisms by which the endocardial structures are predisposed to a bacterial implantation include the formation of eosinophilic necrosis of the valve closure line and thrombotic proliferative and necrotic changes at these sites. Some of these alterations are brought about by the hemodynamics present in congenital and acquired defects. Others are probably due to inflammatory, toxic or degenerative processes. The endocardial alterations, together with intracardiac tension, seem to predispose the endocardial structures of the heart to bacterial implantation by providing suitable means for anchoring transient bacterial invaders. Some of these mechanisms are present in nonrheumatic valves, but less frequently than in rheumatic valves. It does not appear that the vascularization occurring in rheumatic valves plays an appreciable part in the implantation of bacterial endocarditis.

Hyperplasia and Regeneration of Myocardium—MacMahon points out that in cardiac hypertrophy of infants there may be an active proliferation of myocardial elements in addition to growth by enlargement of the individual muscular fibers and that during childhood the muscular fibers of the heart may regenerate following severe injury. Both of these observations are in contradiction to current opinion, which is that hypertrophied hearts of adults may be explained mathematically on the basis of an increase in the size of the individual myocardial fibers and secondly, that painstaking search throughout the myocardium in such cases of cardiac hypertrophy has failed to reveal any positive evidence in the form of mitoses, of true myocardial proliferation. This frequently recorded absence of mitoses is also the most important single fact on which the statement that the muscular fibers of the heart cannot regenerate is based. Evidence is presented in the form of mitotic division of the nuclei of the muscular fibers of the heart to indicate that in cardiac hypertrophy of infants a proliferation of the muscular fibers of the heart can take place and that in severe myocardial injury in children regeneration of myocardial elements can occur.

Effect of Posture on Cardiac Output—Sweeney and Mayerson made 200 determinations on the effect of posture on cardiac output in five subjects. Each subject was observed at intervals over a period of from four to six months. The original Grollman acetylene method and the Gladstone modification were used for the study. There was a consistent decrease in output on quiet standing as contrasted to recumbency. The average change per subject with the Gladstone method ranged from 5 to 26 per cent for all determinations and from 8 to 36 per

cent for paired observations. Greater differences were obtained when the Grollman method was used. Measurement of the acetylene diffusion during the rebreathing procedure gives no evidence of recirculation occurring in the recumbent position within twenty-three seconds. In the standing and sitting positions acetylene diffusion is retarded after about ten seconds, indicative of recirculation. Adequate mixing can be obtained by the Gladstone rebreathing procedure within four or five seconds and consistent results can be obtained by use of this method in the standing and sitting positions. The two methods give similar results in the recumbent position.

Vaccines Against the Common Cold—Bristol gives the results of treatment with standard stock vaccines or serobacterins from cultures of the common pathogenic microorganisms of the respiratory tract in six separate groups of industrial subjects (totaling more than 19,000). The time over which this treatment against the common cold was available to the different groups varied from seventeen to five years. On the whole the study indicates an apparent reduction in the severity, duration and complications of acute respiratory diseases. There is little evidence that such vaccines have materially reduced the incidence of the common cold. To the extent that such vaccines reduce the length of disability and absence from work, they apparently may be of some value in the industrial health program. While no one procedure alone, such as the use of vaccines, should be relied on entirely to build resistance against colds, a broad program of preventive treatment should be encouraged particularly among cold-prone employees, in cooperation with their family physicians.

Diagnosis and Treatment of Perinephric Abscess

The new x-ray sign for the diagnosis of suppurative perinephritis that Mathe discusses consists of renal fixation evidenced by making retrograde or intravenous pyelograms in the reclining

and standing positions. This sign occurs early, is present in all cases, and has been repeatedly verified by operation or by necropsy. It was the only positive x-ray sign encountered in twenty-seven proved cases of perinephric abscess in which a complete urologic examination was made. The early diagnosis and intelligent treatment of suppurative perinephritis depends on a thorough knowledge of all types of cases (primary hematogenous, perinephric abscess secondary to kidney lesions and paranephric abscess secondary to lesions of neighboring organs). Important signs and symptoms are persistent remittent fever, leukocytosis, fulness in the loin or abdomen with a relative paucity of chemical changes in the urine. Corroborative x-ray signs are renal fixation, obscuration of the psoas muscle and kidney outline, displacement of the kidney and ureter revealed by stereoscopic films, opaque shadow cast by abscess, curvature of the spine, displacement of the colon and fluoroscopic evidence of disturbance of respiratory synchronism and the presence of a wave in the cavity of the abscess. Treatment of perinephric abscess consists of prophylactic measures instituted to relieve infectious processes, in order to prevent invasion of the blood stream and later metastatic infection of the perinephrium. Surgical drainage with sufficient exposure to permit search for walled off pockets, examination of the kidney for cortical abscess formation and adequate drainage is recommended. Two stage nephrectomy is advised in grave cases of perinephric abscess secondary to destructive inflammatory processes of the kidney.

Diagnosis and Treatment of Movable Kidney—Herbst believes that to demonstrate ptosis urographically one of the following methods should be used: (1) Urograms must be taken in the prone and upright position, (2) serial urograms should be taken with different phases of respiration (from that of complete expiration to extreme inspiration), (3) the method of serial pyelography practiced by Moore is perhaps the most practical because it can be done with least difficulty, (4) the method of Jarre and Cumming is valuable, (5) the best method is direct fluoroscopy using skodan with retrograde ureteral catheter injection, with the patient in both the prone and upright positions and (6) the ideal method would be motion picture film records of the fluoroscopic visualization following the intravenous administration of some compound that would be excreted in sufficient concentration to render fluoroscopic visualization satisfactory. The treatment of ptosis of the kidney presents individual problems. Nephropexy in properly selected individuals is productive of as large a proportion of satisfactory results as any surgical procedure. The individual with marked ptosis of the third degree with severe symptomatology will not respond to belts or increase in weight and therefore nephropexy should be performed, the following principles being observed: 1. The kidney and upper part of the ureter should be completely mobilized so that, regardless of the position in which the kidney may be fixed, the relationship of the upper part of the ureter and pelvis may allow of proper accommodation. 2. In view of the fact that the production of pain may be prevented by interference with the nerve supply to the kidney, stripping of the nerves from the renal pedicle should be done. Stripping the nerves from the renal pedicle will remedy most of the pain-producing abnormal motility syndromes, which may or may not have been recognized. 3. The bed in which the kidney is to lie should be well cleared of fat so that satisfactory adhesions may form. The height at which the kidney is fixed is not important. The main factor is that it be fixed in a position at which the renal pelvis may accommodate itself satisfactorily to the upper part of the ureter and at which the various forces will have the least possible chance of pulling it downward and again disturbing the ureteropelvic relationship. In the treatment of ptosis of the second degree, conservative methods should be tried before operation is resorted to. When these expedients fail or when definite hydronephrosis develops, nephropexy should be performed. In the first degree of ptosis much patience should be displayed in attempting to relieve the complaint by the putting on of weight, abdominal pads, and the use of the various drugs that control neuromuscular dysfunction. Ureteral dilation will occasionally relieve symptoms but usually calls for repeated dilation. Nephropexy is the procedure of choice in individuals who will not respond to conservative treatment or who have hydronephrosis.

Massive Pleural Effusions in Artificial Pneumothorax

—Rosenblatt states that between 1920 and 1935 there were nine cases at the Tuberculosis Division of the Montefiore Hospital in which a massive effusion occurring in the course of artificial pneumothorax was permitted to remain intact with subsequent abandonment of the pneumothorax. No unfavorable complications materialized and the ultimate results were far better in this group than in the entire group of all pneumothorax cases. One of the important objections to permitting pleural effusions to remain intact is the danger of their becoming purulent. In the seven cases in which the pleural fluid was aspirated there were no instances of empyema. However, in two of them the fluid was turbid. These were the cases in which the greatest number of aspirations was made. Another major objection was that the fluid, if it did not become purulent, would remain unabsorbed for a long period and embarrass the patient's condition in many ways. The patients who were followed up after discharge showed complete absorption of the fluid with only residual thickening of the pleura. Retraction of the trachea or mediastinum was slight and did not cause respiratory or cardiac difficulties. Following the absorption of the fluid no cavities remained opened. On the contrary, the pulmonary disease seemed healed in a most effective manner with only scattered fibrotic infiltrations as scars of the former caseating lesions. Another objection is that the presence of the fluid will result in the formation of adhesions which would prevent the continuation of pneumothorax at a later date if it should become necessary. Whether it was a mechanical or a biologic action cannot be ascertained, but the ultimate results obtained seemed to be final and the question of reestablishing pneumothorax did not arise. The period of active therapy was shortened. While the massive effusion did not abruptly alter the patient's clinical condition the subsequent clinical course was one of improvement. The average duration of active therapy in these cases was far less than for pneumothorax cases in general and the results are far more encouraging. If the patient who had bilateral disease at the time pneumothorax was induced is not considered, all the patients were discharged as improved with negative sputum. Six patients who have been observed from one and a half to ten years after discharge are well and working or able to work. The author is convinced that the prognosis of the patient who has developed a massive effusion in the course of artificial pneumothorax is far better ultimately than that of the patient in whom collapse therapy is continued by removal of the fluid, that is, in dominantly unilateral cases. When the amount of fluid is insufficient to interfere appreciably with pneumothorax refills, they should be continued with no regard to the presence of the fluid, but when the effusion has reached massive proportions so that it is impossible to continue further insufflations the pneumothorax should be abandoned and the fate of the disease left with the effusion.

Tuberculosis of the Lower Lobe—Of their forty cases of tuberculosis of the lower lobe that Weidman and Campbell encountered in a review of the roentgenograms of all patients

admitted to their institution from January 1932 until October 1936 the results were unsatisfactory in nine (eight died), eleven were partially satisfactory, fourteen are satisfactory to date, five have been observed too briefly, all are improving at present and one is untreated. The results considered in the aggregate are far from brilliant, irrespective of the collapse therapy employed. They tend to substantiate the contention that tuberculosis of the lower lobe is still a definite therapeutic problem.

Intracranial Pressure—During the last seven years, Dandy encountered twenty-two cases in each of which the signs and symptoms of intracranial pressure have been indubitable, and yet in none has there been an intracranial tumor or a space occupied by a lesion of any kind. Almost without exception a clinical diagnosis of unlocalized cerebral tumor has been excluded by ventriculography. All these patients have complained of headache, most of them of nausea, vomiting, diplopia, dizziness and many of loss of vision, and objectively in every instance there have been bilateral papilledema and usually hemorrhages in one or both eyegrounds to indicate that intracranial pressure was present. In each case the intracranial pressure has been demonstrated objectively and usually actually measured by ventricular or lumbar punctures. The subsequent demonstration of pressure over a period of months or years is merely a matter of inspecting the site of the subtemporal decompression to which most of these patients were subjected for treatment, with success. The increased intracranial pressure may last only a few months but at times it may persist for years. Curiously the decompression is almost never consistently at its maximal fulness but is intermittent, and the pressure may come and go with surprising rapidity—from one extreme to the other in a few minutes. The cause of the sudden changes—indeed the cause of the increased pressure at all—is unknown. It can be reasoned with safety that the increased intracranial pressure is dependent on the content of the intracranial fluid. The only other possible explanation of the increased pressure is by variations in the intracranial vascular bed, probably by vasomotor control. That the increased pressure usually sets its limit within the bounds of relief afforded by a subtemporal decompression is indeed surprising. The periodic nature of the attacks, and also the permanence of cure of four persons known to have remained well without treatment, lead to the suspicion that this condition may be a common one and that only the most severe grades are encountered by the physician, and that many of the transient, unexplainable headaches may really be instances of this condition though in lesser degree.

Pneumonia Due to Type V Pneumococcus—Rosenbluth and Block discuss their observation in sixty-eight cases of pneumonia due to type V pneumococci among 1,850 cases of pneumococcal pneumonia, giving an incidence of 3.5 per cent. The two impressive features in the incidence of the disease have been a tendency to epidemicity, evidenced by the fact that groups of four or five patients have on several occasions been admitted to the hospital within a few days, and an apparent increase in frequency. This organism, in contrast to many of the new types of pneumococci, must occur rarely if ever as a saprophyte in the mouths of normal persons. In no case was it found except in association with definite pneumonia. Certain factors which appeared to be predisposing were in general similar to those found in other types of pneumonia. Predominant among these was infection of the upper respiratory tract, usually a common cold. This infection was present in thirty-four of the sixty-eight cases. There was a history of exposure in twenty, of trauma in two, of alcoholic stupor in three and of dietary deficiency in three. In three cases pneumonia was associated with pregnancy. In one case, in which pneumonia developed while the patient was in the ward, definite contact infection was evident. Only seven of the sixty-eight patients were women. The ages of the patients were scattered fairly evenly, except in the fourth decade, in which belonged twenty-four patients. The clinical course was characterized by an abrupt onset and a prolonged course, and in more than half the cases there was termination with crisis. Headache, vomiting and jaundice were common symptoms. There was a high incidence of bacteremia and anoxemia. Complications were frequent. In the cases in which serum treatment was given there was a lower mortality than in the cases in which serum treatment was not given. The difference was especially marked when treatment was given early. That group IV pneumonia is always a mild infection is contradicted by the present study.

Shock in Therapeutic Hyperpyrexia—Kopp and Solomon made a study of the severe reactions, considered as shock, that occurred in eight patients during hyperpyrexia induced by hot moist air. These patients were from 19 to 56 years of age. Death resulted in two of this group. The reactions occurred at temperatures of 106 F or above, the body temperature usually showing some further rise during the reaction. The impending shock was ushered in by a sudden increase in the pulse rate, pallor or cyanosis of the skin, a continued or rapid rise in the body temperature, fluttering of the eyelids, twitchings of the muscles of the face or extremities, vomiting or sudden quietness, suggesting coma in a patient who had previously complained bitterly of the heat. Readings of the blood pressure when obtained at this time showed low levels and in three patients the radial pulse was either weak or absent. The pulse rate at the onset was usually rapid. In one patient it increased from 130 to 180. In six patients these initial symptoms were followed by clonic or tonic convulsive movements of the jaw, extremities or trunk, and in five of the latter group the rigidity either localized or generalized, was so marked that it was difficult to differentiate it from the tonic

state of a convulsive seizure or muscular rigors due to heat cramps. In all patients considerable hyperactivity, jactitation and maniacal excitement occurred, and it was necessary to restrain them. This episode was either preceded or followed by coma or delirium or both. Clinical signs of pulmonary edema were present in three patients. The skin of each patient was hot and dry. Sodium amylal or morphine sulfate was administered to five patients of this group before or during fever therapy. Six patients survived the treatment, five recovered, completely in from one to forty-eight hours, with no residual changes or complaints. The sixth patient experienced a stormy convalescence of eight weeks. The mechanism of shock under the conditions of hyperpyrexia consists of a diminution in the blood volume, an increase in the vascular bed and an increase in the vascular permeability. A disturbed neurogenic mechanism, in addition to a disturbed hematogenic mechanism (dehydration), is also present. The presence of alkalosis and hypochloremia during artificial hyperpyrexia modify the clinical picture of the shock syndrome. Treatment should attempt to reduce the body temperature, increase the volume of blood, diminish the capillary permeability and compensate for the alkalosis and the loss of chlorides by (1) the evaporation of lukewarm water from the surface of the body, (2) intravenous infusions and (3) inhalations of carbon dioxide and oxygen.

Carcinoma of the Female Breast—There is no actual proof that preoperative irradiation followed by simple excision of the breast is not as good as preoperative irradiation followed by the complete operation, yet 44 per cent of the patients who had preoperative irradiation followed by the complete operation had demonstrable metastases in the axillary glands, and Cohn thinks that there should be no restriction of the complete operation because of preoperative irradiation. The surgeon will have only one opportunity to cure a patient with carcinoma of the breast. When a clinically benign tumor proves in a frozen section to be cancer or is suggestive of cancer, he has the choice of doing the complete operation at once or closing the wound giving preoperative irradiation and after the proper interval of time doing the complete operation. In the doubtful cases while the irradiation is going on the section can be submitted to other pathologists for their opinions. When the sections show cancer, even though all palpable evidence of disease was completely removed for biopsy, for the present anyway, the author feels that the complete operation should follow. The chances of curing a recurrent carcinoma of the breast are so small that he has about decided no longer to advise operation. Of the forty-one patients with recurrent carcinoma in his series only four are well, and the average length of time since the first operation was admitted to the clinic is only one year. Some of these recurrent carcinomas will be operable and present an apparently favorable prognosis, but the fact alone that they are recurrent almost excludes any possibility of a cure by surgical measures or by preoperative irradiation and surgical treatment. Perhaps even in this group it may be wise to treat by irradiation only.

True Branchiogenic Cyst and Fistula of the Neck—Meyer discusses the embryology of the branchial area and presents the case of a boy of 9 in whom after the removal of a branchiogenic cyst the tract was opened and found to be lined with normal appearing skin and to be firmly attached to the styloid process. Microscopically, as was shown by the photomicrographs, the wall of this tract contained all the appendages of the skin, as hair follicles, sweat glands and sebaceous glands, that is, the growth was a true branchiogenic cyst and tract originating from the second branchial arch. Complete removal of this brought about a cure of the condition.

Chronic Gallbladder Disease—In addition to operating on 143 patients himself, Niemeier studied 529 operations on the biliary tract performed at the Hamilton General Hospital. An estimation of the mortality rate in each ten year group, in these and several other series of cases, shows a progressive rise in each decade, undoubtedly due in part to advancing age and to the more advanced stage of the disease, as operative and pathologic observations suggest a long duration of the disease in these older patients. That many of the patients could have been operated on earlier with a lower mortality is indicated by the fact that in a number of them the history extended back over a long period of years. Ninety-nine patients, or 69 per cent, postponed operation until they were driven to it by unbearable pain or some acute emergency or serious complication. As most of the patients had been under the care of physicians from time to time, and the diagnosis of disease of the gallbladder had been made in the majority, it is apparent that the tendency of the patient to delay is but a reflection of the attitude of the physician toward chronic lesions of the gallbladder. Many physicians believe that chronic latent disease of the gallbladder is a harmless condition for which surgery is not indicated unless some acute manifestation or alarming complication develops. The prevalent policy of delay in the surgical treatment of chronic disease of the gallbladder also results in damage to adjacent organs such as the liver and pancreas. Hepatitis can frequently be seen in the gross and is often visibly more marked in the immediate vicinity of the gallbladder. Once destructive changes have occurred in adjacent organs, the patient, even after cholecystectomy, will be left with permanent damage. In addition to local effects of neglected chronic disease of the gallbladder, there are other insidious and more widespread effects. Many patients with apparently latent lesions pay the penalty of delay in the form of damage to distant organs. Literature has accumulated regarding the diseased gallbladder as an etiologic or aggravating factor in systemic disease. Statistical, pathologic and clinical evidence all emphasize the importance of earlier surgical treatment of chronic disease of the gallbladder. With modern diagnostic methods, earlier recognition of the condition should present little difficulty.

Treatment of Keratitis Neuroparalytica—MacMillan and Cone blocked the canaliculi, preventing the escape of tears into the lacrimal sac and drying, in one case with neuroparalytic keratitis. The corneal lesion healed promptly. The satisfac-

tory result following closure of the canaliculi has been maintained for five months. It is comparable to the results described by Beetham after he had closed the ducts in patients with filamentary keratitis. The canaliculus was slit with the actual cautery, it closed permanently, and therefore such a procedure would seem to be the one of choice. If the important factor in the development of corneal lesions is diminished secretion, it should be possible by detailed physiologic tests to select the cases in which this complication is apt to develop and to prevent it.

Unusual Manifestations of Some Brain Tumors—Dyrenforth discusses two clinical manifestations of cerebral tumors that are remote from the ordinary diagnostic procedures. The first of these is the definite neoplastic entity known as oligodendroglioma. The most important sign in these tumors is the presence of lime salts. Even in the earliest forms they tend to become cystic and promptly form calcareous deposits which are opaque to x-rays. This condition is of importance in the demonstration of such a tumor. The presence of characteristic opacities in roentgenograms of this brain tumor is significant enough for diagnosis, particularly since it is a cerebral type of growth. Other clinical changes must, of course, be considered: papilledema of low grade, xanthochromic cerebrospinal fluid, increased intracranial pressure and various neurologic signs. But while these are characteristic of numerous cerebral lesions, the x-ray demonstration of calcific deposits in a cystlike formation in the cerebrum, ordinarily unilateral, would be diagnostic of this particular tumor. In view of its operability this is considered an important item. The other manifestation offered for consideration is that of peptic ulcer. More specifically this is a lesion of the prepyloric area, but there is recognized a closely related neurogenic theory of origin. But this has to do with damage to the extranuclear vagus and sympathetic systems, whereas the idea proposed by the author is that of cerebral damage, specifically from neoplasm, and the resulting influence on the gastric secretion. To this group are related also the experimental results with pharmacologic methods, namely, injuring the base of the brain by injecting epinephrine into animals and causing overstimulation of the sympathetic system with the production of gastric and duodenal erosions. A parasympathetic center in the diencephalon or interbrain is suggested, from which fiber tracts pass backward and form a relay with the nucleus of the vagus nerve, among others, and thus therefore accounts for the influence on the alimentary canal of lesions in this area. Cushing finds that lesions anywhere along the course from the anterior hypothalamus to the vagal center may cause gastric lesions. The result may be from parasympathetic stimulation or from "vagal release" due to sympathetic paralysis. Since intracranial injuries and diseases of this portion of the brain are known to produce lesions of the gastric mucosa, he concludes that such conditions following certain of his cerebellar operations are of identical nature. Cushing goes on to say that this evidence of involvement of the medullary center or a minor involvement of the interbrain may well explain the presence of a long overloaded station for vegetative impulses easily affected by psychic influences—that highly strung persons of nervous

instability classified as vagotonic are prone to have chronic digestive disturbances with hyperacidity often leading to ulcer. The fact is stressed that cerebral tumors are frequently the cause of this condition whether directly, by mechanical influences or indirectly, by reason of surgical influences.

Dangers of Rapid Diuresis—Barker points out that, with the improvement of diuretic management, edema as such is much more readily controlled and one is too frequently tempted to watch the volume of urine or weight drop without sufficient regard to the concentration of the waste products that may be less easily eliminated. Edema is only a symptom and the fundamental problem must not be slighted. The volume of fluid in the edematous patient is frequently much larger than one's greatest estimate. This fluid must be cleared through the kidneys and often either the long standing passive congestion or actual renal vascular disease or both alter greatly their ability to clear minerals and waste products of protein metabolism. Nature's dilution of retained materials is often a most important physiologic safeguard. The reverse of the process therefore becomes a most important matter to such patients unless careful observation is maintained. The great benefits derived from a physiologic diuresis cannot be emphasized too greatly. The fact that drugs usually are quite evenly distributed through the fluids of the body makes diuresis an element of danger in some cases. This is true of digitalis. One must be alert to the urgent need for the control of diuresis by an active antidiuretic plan.

Intrathoracic Calcification in Tuberculin-Positive Infants—Brailey obtained the 158 cases for her study from the patients admitted to the special clinic for childhood tuberculosis of Johns Hopkins Hospital between Nov. 1, 1928, and Nov. 1, 1933, all of whom at time of entry into this study (1) were less than 2 years of age, (2) were tuberculin positive, (3) showed on x-ray examination no evidence of calcification and (4) have since been followed with serial roentgenograms for periods ranging from less than one to more than five years. Calcification appeared in the chest in about 17 per cent of children observed one year after the discovery of tuberculous infection. This proportion rose to 47 per cent by the end of two years, to 62 per cent by the end of three years and to 66 per cent by the end of four years. White and Negro children

developed calcification at equal rates, but the Negro children had unhealed lesions associated with first calcification in 55 per cent of the ninety-eight cases and the white children in 30 per cent of the sixty-five cases. The proportion of cases in which calcification appeared varied with the extent of the lesion. Within a period of four years it was observed in 86 per cent of children who had shown parenchymal lesions, in 67 per cent of those who had shown definite involvement of the tracheobronchial node without parenchymal lesions, and in 36 per cent of those in whom no definite lesion had ever been recorded. In 90 per cent of the cases calcification appeared first in the tracheobronchial lymph nodes. Associated calcifying pulmonary nodules were observed simultaneously in about one third of these cases, and in another third pulmonary nodules appeared later. About one fifth of the cases in which calcification developed had shown no definite lesion in earlier x-ray studies. In the remaining four fifths, calcification usually took place on the side of the thorax at which the active lesion had been noted, but in 9 per cent it appeared only on the opposite side, where no lesion had been seen. Serial roentgenograms demonstrate that small deposits of calcium may become indistinguishable with time, owing to changes in the calcified mass or to its becoming hidden by mediastinal structures. An instance is cited of the absorption and disappearance of a calcified parenchymal nodule within four years of its first appearance. Of forty-six patients in whom calcification had been noted more than two years previously, tested recently with old tuberculin with the possible exception of one patient failing to react to 0.01 mg and not retested, no instance of loss of allergy has been found.

Response to Tetanus Toxoid One Year After Immunization—Jones and Moss tested the blood specimens of forty-one subjects for antitoxic content six months and twelve months after injections of tetanus toxoid. There was a noticeable drop in titer after six months and twelve months in the two groups that received three injections (0.1, 0.2 and 0.2 cc) and two injections (0.2 and 0.3 cc.) of alum toxoid respectively, while the titer of the group that received three injections (0.5, 1 and 1 cc.) of untreated toxoid remained fairly constant. Apparently while alum precipitated toxoid produced a greater and more rapid immunity, the immunity dropped over an extended period.

to the level stimulated by untreated toxoid. A subsequent dose of tetanus toxoid or tetanus alum precipitated toxoid one year after primary injection increased the antitoxic content of the blood from twenty to fifty times, making a level which is higher and more persistent than that produced by a prophylactic injection of tetanus antitoxin.

Calcium Tolerance Curves in Paget's Disease of Bone—London and Bernheim performed 201 calcium tolerance tests on 146 persons, including seventeen patients with untreated Paget's disease of the bone and twenty-two normal subjects. Subjects were instructed to come to the hospital fasting and were given a little chocolate to eat in order to avoid unpleasant reactions, which are likely to follow the intravenous administration of calcium to a fasting subject. From five to ten minutes afterward an initial blood specimen was withdrawn and a uniform test dose of 10 cc of 20 per cent calcium gluconate solution (0.186 Gm of calcium) was injected slowly, during four to five minutes. First and second specimens were withdrawn fifteen minutes and two hours after the injection for analysis. It appears that the calcium curve of Paget's disease is notable for an absence of marked deviation from the pre-injection level. The curve obtained in Paget's disease, in view of its tendency to resist marked upward deviation, would appear to indicate an increased affinity for calcium on the part of the bones and other tissues or a decreased affinity for calcium on the part of the blood. The former interpretation is in line with the metabolic studies reported by several investigators, showing a retention of calcium by the body in Paget's disease of the bone. In five cases of Paget's disease an almost flat curve was obtained. This was not obtained in any of the normal subjects.

Iron Metabolism in Hemochromatosis—Fowler and Barer carried out iron-balance studies on four patients who presented the characteristic features of hemochromatosis and as a control similar studies were performed on two patients with uncomplicated diabetes mellitus whose diabetes was of approximately the same severity as that in the patients with hemochromatosis. Three patients with advanced stages of

hemochromatosis retained no more iron than did two patients with diabetes mellitus. This was true not only when the iron was obtained from the food alone but also when an additional 340 mg of iron was given in the form of iron and ammonium citrate. This shows that in the late stages of hemochromatosis there is no abnormal retention of iron. The results obtained in the other case are more difficult to interpret, since the studies were of short duration. For the single period of observation an unusually large retention of iron occurred, distinctly greater than that in other cases of hemochromatosis or control subjects. It is obvious from the results of tissue analysis that retention of unusually large amounts of iron must occur at some time in the development of hemochromatosis. The clinical recognition of the disease is difficult or impossible in the early stages before evidence of pigmentation, cirrhosis of the liver and diabetes make their appearance, so that iron-balance studies will be difficult to obtain at that time. The authors encountered one patient in a relatively early stage who had entered the hospital because of an unrelated condition. He presented moderate pigmentation of the skin, slight enlargement of the liver and no glycosuria but a diminished tolerance to dextrose. The results from this patient cannot be considered as conclusive but suggest that iron is retained in excessive amounts in the early stage, although this abnormal retention does not persist in the fully developed case.

Effect of Yeast on Liver Glycogen During Hyperthyroidism—Drill studied the change that occurred in the percentage of liver glycogen in hyperthyroid rats, if any, when small amounts of thyroxine were injected daily over a longer period than six days as used by Abelin, Knochel and Spichtin. Yeast, in which vitamins B and G are known, was fed in order to produce a constant weight, or a gain in weight, in rats receiving thyroxine and the liver of these rats was then analyzed for the percentage of glycogen and compared with control rats. A group of rats on a normal daily diet containing from 21 to 24 U S P units of vitamin B (B₁) and from 24 to 26 Sherman units of vitamin G gained in weight and showed normal values of liver glycogen. A group of rats on the same normal diet receiving daily 0.1 mg of thyroxine subcutaneously lost weight eventually and showed low values for liver glycogen. A group of rats on a normal daily diet containing 54 U S P units of vitamin B and 60 Sherman units of vitamin G and receiving 0.1 mg of thyroxine subcutaneously

still gained or remained constant in weight and showed normal values for liver glycogen. The change in the vitamin content of the diet of the test rats, as regulated by the amount of yeast, is responsible for the normal value of liver glycogen.

Protein Deficiency Edema—Edema may not only be cardiac or renal but also mechanical or obstructive, inflammatory, allergic and nutritive. It is the edema caused by a reduction in the colloid osmotic pressure and in particular that termed nutritional edema, protein deficiency edema, that Boyer discusses. Of the two types of protein having a part in the production of protein deficiency edema, albumin and globulin the former is of the greater importance. Serum albumin is of greater importance because it exerts an osmotic pressure four times that of the serum globulin. Although for many years the level of serum proteins was definitely associated with the appearance of edema, it has not been until more recent years that this has been recognized in cases other than the so called nutritional edema. The treatment of protein deficiency edema consists primarily in the administration of protein in large quantities. However, water without salt cannot be retained. In many cases when the serum proteins are at the borderline, that is, when they are at or slightly above the critical level, edema will appear. In these cases the simple restriction of salt from the diet will result in the disappearance of edema. Therefore in treating this type of edema it would appear best to give not only high protein diets but also a salt free or salt low diet with restriction of fluids. The amount of protein given daily should be from 100 to 150 Gm. Animal protein will secure more rapid and satisfactory results and the control of salt and water intake with rest in bed is advisable. It is possible to compute the amount of protein necessary by giving 1 Gm of protein per kilogram of body weight plus that which is lost in the urine if that is the route of protein deprivation. Blood transfusions and the intravenous administration of acacia dextrose are to be resorted to when nothing can be taken orally. The use of mercurial diuretics is questionable and cer-

tainly one should defer their use if there is the slightest question of existent renal damage. Ammonium chloride and other salts may be used in an attempt to upset the electrolytic concentration and thus produce diuresis. Edema is a symptom and sign, not a disease, to be interpreted as part of a disease process with the treatment incorporated in that of the original disease.

Primary Pneumococcal Meningitis—McDonald and Korb report four cases of primary pneumococcal meningitis. In every case lumbar puncture showed intracellular pneumococci in the spinal fluid. In no case did routine examination reveal evidence of a primary pneumococcal infection in the ear, the chest or any part of the body, to which the meningitis might be secondary. The onset was insidious. Nerve signs developed rapidly. Violent motor display was quite characteristic. Death came not later than the third day with respiratory failure. The average duration of the course of the disease was less than three days.

Technic of Appendectomy—Ochsner and Lilly declare that the inversion without ligation technic is the ideal appendectomy procedure provided the stump can be inverted without contamination of the peritoneal cavity and that hemostasis can be secured. In the technic that they describe, this is accomplished by applying three crushing forceps to the appendical stump and by grasping the crushed sealed stump before the last forceps is removed prior to inversion. Hemostasis is secured by introducing a purse-string suture in such a way that an intramural branch of the appendicular artery is grasped.

in the suture. Because the crushed stump is inverted into the lumen of the cecum, there is no danger of subsequent inflammation occurring around this stump and extending to the cecal wall or peritoneal cavity.

Jaundiced Patients—Best and Hicken believe that it is dangerous to accept the recognized criteria for a patent cystic duct in those jaundice cases which are associated with a malignant condition of the head of the pancreas or the lower end of the common duct. If one cannot definitely insert a probe through the cystic duct and into the common duct, there are two alternatives: either an immediate cholangiogram can be made to determine the exact status of the cystic duct, or the common duct can be directly attacked either by choledochostomy or choledochoduodenostomy. If the cholangiogram proves the cystic duct to be obstructed, the latter procedure is indicated. If a probe cannot be directed through the cystic duct, immediate cholangiography is not indicated in most instances but an attack should be made on the common duct for biliary decompression. Three cases are reported in which biliary decompression was not accomplished because of obstruction of the cystic duct and the patients died because of the extra load of operation. These cases also demonstrate the unreliability of a patent cystic duct unless a probe can be inserted through the duct. Although drainage of the common duct and duodenal anastomosis of the common duct are technically more difficult than utilization of the gallbladder, the mortality rate is decidedly lower. Reestablishing the flow of bile from the liver to the gastrointestinal tract becomes a vital necessity when the intrinsic or extrinsic obstruction that is blocking the lower end of the common duct cannot be removed. Many times a two stage procedure is necessary: short circuiting or drainage to relieve the jaundice and improve the general condition of the patient, and the removal of the obstructive agent.

Autohemotherapy in Treatment of Psoriasis and Herpes Zoster—The method that Barksdale employed in treating two cases of psoriasis and seven of herpes zoster entailed the removal of 6 or 8 cc of blood from the cubital vein and injecting it immediately into the gluteal muscle before it had time to clot. The two cases of psoriasis responded well to a routine consisting of autohemotherapy, anthralin ointment locally and a diet rich in milk and butter. Autohemotherapy not only shortens the duration of pain of herpes zoster but also shortens the course of the disease. It is as good as any other form of therapy that has been used in the past, if not a specific in the treatment of herpes zoster. The majority of patients gave a history of the absence of milk or butter from their diet. Patients with psoriasis were advised to partake of a diet rich in milk and butter, supplemented by carotene in oil or cod liver oil, the local application of anthralin ointment, which is a chrysarobin derivative, ultraviolet radiation and autohemotherapy.

*Pernicious Anemia with Diabetes Mellitus H G McGregor—p 617

Pernicious Anemia with Diabetes Mellitus—McGregor presents two cases of pernicious anemia in association with diabetes mellitus. There are certain conditions common to the two which might predispose to their simultaneous occurrence. A point about which there is no clarity is whether the diabetes should be considered as a complication of the anemia or vice versa. In case 1 the pernicious anemia was known to have preceded the diabetes, in case 2 it was probably the reverse, and in the majority of reported cases it was the diabetes that developed first. Figures as to the frequency of the association of the two diseases are suggestive of something more than chance, but they are no more than suggestive. Though achlorhydria, longer duration of life because of improved treatment, the factor of middle age and hereditary tendencies are factors common to the two diseases, especially when diabetes is the primary condition, there still remain cases in which pernicious anemia was the first to develop. In the latter circumstance certain changes in carbohydrate metabolism that are known to occur in anemia seem more likely to be the agents which lead to the two diseases. Evidence is contradictory and no adequate explanation has been offered regarding the mechanism of production of high blood sugar and abnormal sugar tolerance in pernicious anemia or the occasional occurrence of pernicious anemia complicating diabetes. Most authors consider that the phenomenon is a chance combination.

Cerebral Edema in Certain Mental Disorders C Lovell—p 656
*Nonsuppurative Intraaural Complications of Otitis Media A A McConnell—p 659

Thoracoplasty with Extrafascial Apicolysis—Semb maintains that to produce a free mobilization of the upper lobe in selective collapse the thoracoplasty should generally be combined with apicolysis. His method of apicolysis is characterized by three chief points: (1) apicolysis in the extrafascial plane by cutting the so called suspension bands of the lung sharply or bluntly, (2) a radical rib resection according to the extent of the apicolysis and (3) preparation of an extrafascial space by cutting the periosteum of the ribs and the other tissues in such a manner that they are not loosened from the surface of the lung. This extrafascial type of apicolysis gives both relaxation and subsequent fixation of the collapsed part of the lung. His follow-up examinations have shown that the cavity closes gradually by retraction in the course of weeks or months following operation. An extensive local block anesthesia—with 0.5 per cent procaine hydrochloride and 1:2,000 pontocaine hydrochloride—has been used successfully. In the first stage from three to five upper ribs are resected, usually the whole of the first, most of the second, and decreasing lengths of the third and fourth ribs. The apicolysis is carried out as an open dissection. The intercostal bundles, nerves, vessels and the periosteum of the upper ribs are cut. The adhesions or bands between the apex of the lung and the neurovascular trunk, the

vertebrae and the mediastinum are dissected free and severed. The intercostal bundles are usually excised, as they are liable to necrosis. The resection of the subjacent ribs is usually performed in one or more later stages. Simultaneously parts of the anterior stumps of the previously resected upper ribs are usually resected. The best time for the second stage is within four weeks. Later the regenerated ribs are resected, and sometimes two or three transverse processes. The extent of the operation in each case should be in accordance with the localization of the cavitation, so that the collapse becomes as effective—and at the same time as limited to the diseased part of the lung—as possible. An exact roentgenographic localization of the cavity in two planes is therefore necessary. The usual first stage varies between resection of three to five ribs and apicolysis from a posterior incision. The first stage may be performed as a resection of the anterior parts of the first and second ribs only. The apicolysis is then performed from behind in the second stage. The mortality rate within two months of operation has been reduced to about 3 per cent by operation in several stages. Collapse of the cavity and a sputum free from tubercle bacilli have been achieved in about 90 per cent of the surviving patients. Of all the cases 90 per cent had partial thoracoplasty with resection of eight ribs or less. Only 10 per cent required total thoracoplasty. In seventeen cases artificial pneumothorax had been induced on the other side and was present during the thoracoplasty. These patients tolerated the operation surprisingly well, probably because of a stabilized mediastinum. There were no deaths. In fourteen of the seventeen cases complete collapse of the cavity and a sputum free from tubercle bacilli was achieved. In four cases artificial pneumothorax on the other side was induced after the thoracoplasty. The operation has also been tried after thoracoplasty performed previously by other methods has failed to produce complete collapse. Complete collapse of the cavity was achieved in fourteen of sixteen patients who were operated on a second time in this way.

Nonsuppurative Complications of Otitis Media—McConnell classifies intracranial complications of otitis media as suppurative and nonsuppurative. Nonsuppurative complications are of two kinds, one an encephalic lesion which gives rise to both focal and general symptoms and the other a derangement of the amount or of the circulation of the cerebrospinal fluid, resulting in the accumulation of the fluid and a rise in the general intracranial pressure. When symptoms and signs of increased intracranial pressure develop in the course of otitis media and clinical methods fail to establish a definite diagnosis, ventricular puncture is safer and more informative than lumbar puncture and should be used first. If a communicating hydrocephalus is found, lumbar puncture may then be used for treatment.

Streptococcus in Milk Stored at Atmospheric Temperatures—Pullinger and Kemp tried to determine whether *Streptococcus pyogenes* can multiply in milk stored under normal conditions. The main commercial grades of milk have been investigated, i. e., raw (graded and ungraded), pasteurized

and sterilized milk. It was found that *Streptococcus pyogenes* multiplies readily in sterilized milk stored at 22 and 18 C, and more slowly when stored at 15 C. In fresh raw milk this organism begins to multiply slowly only after from forty eight to seventy-two hours of storage at from 18 to 22 C. In laboratory pasteurized milk the result is similar, but both commercially pasteurized milk and raw graded milk bottled for distribution sour too rapidly for multiplication to take place after artificial contamination. These facts suggest that widespread epidemics are rarely due to extensive multiplication of *Streptococcus pyogenes* in milk during commercial or household storage. The initial degree of contamination of milk with *Streptococcus pyogenes* has no influence on this organism's ability to multiply during storage. The failure of *Streptococcus pyogenes* to multiply during storage is due to its natural reluctance to grow at atmospheric temperatures, the bacteriostatic action of the milk and the readiness with which saprophytic bacteria multiply at atmospheric temperatures. Infected cows play a major part in the spread of milk-borne *Streptococcus pyogenes* epidemics. Routine investigation of apparent milk-borne epidemics should include the immediate bacteriologic examination of an individual sample of milk from every cow concerned in the supply under suspicion.

- *Injuries of Frontal and Ethmoidal Sinuses, with Especial Reference to Cerebrospinal Rhinorrhea and Aerocele H Cairns—p 589

Injuries of Frontal and Ethmoidal Sinuses—Cairns divides cases of cerebrospinal rhinorrhea into four groups: those that occur in the acute stage of a head injury, those that occur as delayed complications of a head injury, those produced during operation on the cranium or the accessory sinuses and cases of spontaneous cerebrospinal rhinorrhea. In addition he considers cases of brain abscess, meningitis and intracranial aerocele that arise as a result of injury to the frontal and ethmoidal sinuses. He gives cases that illustrate the various ways in which cerebrospinal rhinorrhea and intracranial infection may occur after fractures of the frontal and ethmoidal sinuses produced by violent impacts on the forehead or face. In some cases, and particularly in airplane accidents, the upper and lower jaws are also fractured, and there is dissolution of the bony connections of the facial bones to the base of the skull. In fractures of the frontal sinus and cribriform plate there is serious risk of intracranial infection not only immediately after the accident but also at a later period, when any new catarrhal infection of the nasal passages may break through barriers weakened by previous injury. Infection usually takes the form of leptomeningitis, but sometimes it may spread through the substance of the brain, producing abscess of the frontal lobe or purulent ependymitis. More active measures should be exercised in repairing the injured dura by means of transfrontal operation and sutures, or fascial grafts. The indications for urgent surgical intervention are clear in cases of injury to the dura during intranasal operation on the ethmoidal and sphenoidal sinuses and in cases of delayed cerebrospinal rhinorrhea and aerocele following head trauma. In the acute stage of frontal and ethmoidal injuries the case for immediate operation has not yet been clearly established. Greater accuracy of diagnosis of the side and site of injury to the cranial base is necessary before immediate operation, with the attendant risk of aggravating shock already present, can be justified. Much can be done along these lines by more thorough roentgenography of the anterior cranial fossa. Congenital deficiencies in the cribriform plate may contribute to the production of cerebrospinal rhinorrhea, both spontaneous and traumatic, and these also can be disclosed by roentgenograms.

- Deaf Mutism of Traumatic Origin Case C S Hallpike—p 661
*Tuberculous Ulcerations of Mouth and Pharynx F C Ormerod—p 675

Tuberculous Ulcerations of Mouth and Pharynx—In analyzing the cases seen at Brompton Hospital in the last fifteen years, Ormerod has found statistics of nearly 17,000 cases referred to the throat department, in about two thirds of

which there was tuberculous infection and, in the others, a nontuberculous condition of the chest. During this period there were 3,120 cases of tuberculosis of the larynx. There were twenty cases of tuberculosis of the tonsil, thirty-two of the pharynx, four of the postnasal space and two of the lips. He has analyzed more critically the cases seen in the last five years, of which there were twenty-one of tuberculosis of the mouth and pharynx. Patients having tuberculous lesions of the mouth and pharynx are slightly younger than those having disease of the larynx, mostly being from 20 to 30 years of age. The patients with laryngitis live longer, and they may overlap into the next decade, so the incidence is probably much the same. Tuberculous disease in the pharynx and mouth is nearly always a complication of severe disease in the lung. It is a bad sign and shows that the patient's resistance to the disease has broken down. Of the twenty-one cases, both lungs were involved in nineteen, and in many cases all three zones of the lungs were implicated to some degree. Examination of the sputum was positive in fifteen, negative in three and there was no record of it in three others. It was perhaps positive in two of these. The larynx was not involved in six cases. In one case there was congestion of the vocal cords, and in two there was swelling of both ventricular bands. In the remaining twelve there was severe laryngeal disease. In appearance these ulcers are flat with an irregular edge, not deep. They have a slightly undermined edge, the base is granular and covered with tenacious mucus. These patients suffer from a great outflow of mucus, one of their major troubles, necessitating perpetual spitting and swallowing. The presence of mucus on the base of the ulcer assists the diagnosis. The chief symptom in the pharyngeal cases is the extreme pain, so that swallowing is difficult. Ten cases are presented that illustrate some of the types of ulcerations that are encountered.

Role of Appetite in Control of Body Weight—MacLagan gave an unlimited amount of food to rabbits for six hours each day and measured the actual amounts of food eaten in relation to physiologic and pharmacologic influences. Rabbits are little affected by psychic influences and their appetites are quite unimpaired by any incidental manipulation. Mechanisms possibly involved in the normal regulation of body weight are discussed, special stress being laid on the control of the appetite as the most important single factor. Appetite is defined for the present purpose as the amount eaten in a standard time when an unlimited diet is presented to the animal, and it is not intended to denote a psychologic state. A study has been made of the appetite in rabbits with the following results. The appetite normally reaches a maximum after a fast of eighteen hours. It is increased above this maximum by a period of undernutrition. A simple fast of longer (or shorter) than eighteen hours reduces the appetite. The effects of various drugs on the appetite have shown that insulin is the only one on the plus side. Pitressin and atropine had to be given in rather large doses to produce any effect, the former caused slight diarrhea in three of eight animals and the latter gave full dilatation of the pupils.

Inhibition of Menstruation with Testosterone Propionate—Zuckerman observed that the administration of 25 mg of testosterone propionate twice a week to normal mature female rhesus monkeys stopped the menstrual cycle during the period of injections (up to seven months). The internal reproductive organs were not injured by the treatment, and in one animal menstruation recurred about a week after the last injection. Follicular growth and luteinization were both inhibited. Apart from enlargement of the clitoris, no other significant clinical changes occurred. It is suggested that testosterone propionate may be of clinical value for the induction of temporary sterility and the control of uterine bleeding.

Infective Warts in Workers Using Bone Glue—McLaughlin and Edington report an outbreak of warts that occurred in a cardboard box factory. On investigation nine girls were found to have warts, mainly on the dorsal aspect of the hands and fingers, especially on the skin just proximal to the knuckles. All nine girls during their work came in contact with bone glue. Two other girls who also worked with glue had no warts. It was learned that warts on the hands of a worker were first noticed about three years previously, and nearly all the affected girls gave a history of having had recurrent warts for at least two years. Clinical experiments were made on two groups of volunteers (four in each group). One group was treated with glue obtained from the pots of glue used by the girls at their work, and the other group with glue which was of the same variety (obtained from the factory stock) but was made up in the laboratory and had not been handled by any of the workers. The glue in each case was applied once a week to the back of the left hand, where it was well rubbed in and left in place for three or four hours. It was established that the pots of glue in use in the factory had been infected with wart virus and were being reinfected by girls who had warts on their hands. Therefore all girls suffering from warts were taken away from the work involving contact with glue and sent to the hospital for treatment. They were not allowed to handle glue until the warts had disappeared entirely. No fresh or recurrent cases have arisen since this procedure was adopted. It is concluded that the glue became infected while it was on the working benches, because here it was at a temperature below the lethal point for the wart virus. The original infection had probably been introduced by the first infected worker who had had her hands infected outside the factory.

*Immunization Against Typhoid Fever by Means of a Single Injection of Typhoid Endotoxin Vaccine. E Grassel, W Lewin and T van der Merwe —p 660

Immunization Against Typhoid—Grassel and his associates prepared a batch of typhoid endotoxin vaccine with an antigenic concentration about 60 per cent higher than the vaccine administered in two injections, 0.75 cc. of which was injected subcutaneously in the deltoid region in a group of

thirty-nine young European adults. After fourteen days the average H agglutinin titer in the serum of the inoculated persons was 1,500, and the average O titer 1,400. The average titers three weeks after the inoculation were 1,000 and 1,400 respectively, and after four and one-half months the corresponding titers were 1,200 and 1,75. Thus a single injection of this vaccine produced an average O agglutinin titer higher than that produced by the vaccine of less antigenic content, but the H titers showed no gross difference. The average agglutinin titers produced by the single injection of the vaccine of higher antigenic concentration, however, dropped more rapidly than those produced by three injections of the weaker vaccine. Six non-European adults were inoculated subcutaneously in the deltoid region with 0.5 cc of endotoxoid vaccine the antigenic concentration of which was double that used in the group of thirty-nine Europeans, and thirty-four non-Europeans from 7 to 15 years of age were inoculated subcutaneously with the same vaccine. The dosage for children up to 10 years of age was 0.2 cc, and for the remainder 0.3 cc. At the same time a further group of similar ages was inoculated by means of two injections of the vaccine of 60 per cent lower antigenic concentration. No gross difference in the clinical reactions was observed between the two groups. Moderate local reactions were observed, but there was no marked general disturbance. On the results obtained from these preliminary experiments a field trial was made of the single injection method for typhoid prophylaxis. An experiment was conducted on the non-European labor complement of the Van Ryn Deep Gold Mine. The endotoxoid used was of similar antigenic concentration to that injected into the thirty-nine European adults. The mine laborers, however, were given 1 cc subcutaneously in the pectoral region. At the end of July 1937, 5,445 individuals of a total personnel of 6,652 had been so treated. In no case did the inoculation cause a reaction sufficient to prevent the laborer from continuing his work. Nine cases of typhoid occurred after immunization by the single inoculation method had been instituted. Of these, eight occurred in uninoculated persons with two deaths, and one in an inoculated person, a nonfatal case. The latter person, however, had been inoculated only four days before his admission to hospital suffering from the disease. During 1936 a total of fifty-two cases of typhoid occurred, all of them in uninoculated individuals. The similarity of the results obtained in this investigation to those of large scale immunization of non-European Rand mine laborers by means of two injections of typhoid endotoxoid vaccine suggests that the single inoculation method has proved efficacious in the prevention of typhoid. These preliminary results justify an extensive field trial in which the two methods can be strictly compared. It appears that a single injection of typhoid endotoxoid vaccine of high antigenic concentration produces a definite degree of immunity. The duration of the immunity afforded is, however, unknown.

Inhibitory Effect of Saliva on Tubercle Bacilli—Piasecka-Zeyland and Zeyland examined the direct action of human saliva on tubercle bacilli. They repeated the experiments many times, using the saliva of the same subjects to check the results in order to convince themselves of the indicated fact that human saliva exerts an inhibitory effect on the growth of tubercle bacilli. The protracted heating at 56°C of the saliva is without any influence on the observed inhibitory effect. They believe that the decrease in the numbers of colonies after treatment with saliva is not the result of an agglutination of the bacilli by the saliva. At present the experiments allow them to conclude that in certain circumstances the addition of human saliva inhibits the growth of tubercle bacilli. This effect depends not only on individual variations but also, in a minor degree, on unknown factors, as is evident by slightly varying results in the particular experiments.

*Transmural Injection of Iodized Oil for Preoperative and Postoperative Exploration of Large Pulmonary Abscess P Pruvost and J Quenu—p 1025

Transmural Injection of Iodized Oil in Pulmonary Abscess—Pruvost and Quenu decided to inject iodized oil by means of a needle through the thoracic wall. This method is not entirely new, but it has been criticized as often unsuccessful and not exempt from such risks as hemorrhage, the extension of infection and gaseous embolism. The authors, however, cite reports from the literature and three cases of their own observation in which the injection of iodized oil through the thoracic wall proved simple. The injection of a small quantity of the opaque oil gives exact information about the location and the form of the cavity. It is advisable not to inject more than 10 cc. A comparison of roentgenograms made with and without the contrast medium clearly demonstrates the superiority of those made with the opaque oil. On the basis of the precise information provided by them, it was possible to establish in each case the best way of approach and the shortest and most favorable route for drainage. After the operation the oil is injected through the drain to observe the gradual filling up of the cavity and the selection of the best time for the cessation of the drainage. To free the method from possible risks, it is essential to select the cases carefully and not to neglect essential precautions. The puncture should be made only after a complete clinical and roentgenologic examination of the patient, which reveals an abscess of considerable size and of relatively superficial location. It is essential to select with care the site of puncture. The needle should not be too thick, in order that the oil may pass easily, it should be sufficiently heated. It is necessary to aspirate with the syringe while the needle is introduced and while it is withdrawn. Iodized oil should be injected only if purulent fluid is withdrawn or if there is an odor. Iodized oil is well tolerated. A part of it is expelled through the bronchial passage during the hours following the examination. The remainder is gradually evacuated or absorbed. The authors reach the conclusion that this transthoracic injection of iodized oil is a valuable aid before and after the operation for a large pulmonary abscess.

*Efficacy of Intravenous Injections of Sodium Bromide and of Atropine Sulfate in Treatment of Gastric and Duodenal Ulcer A Landau and W Heyman—p 1468

Sodium Bromide and Atropine Sulfate in Gastric Ulcer—Landau and Heyman resorted to the use of sodium bromide and atropine in three refractory cases of gastric ulcer. The sodium bromide was given intravenously in doses of 10 cc of a 10 per cent solution and the atropine sulfate was given in doses of 1 mg. The first patient was given forty-nine injections in all and the other two received twenty-seven and fifteen, respectively. The patients tolerated the injections well. Occasionally they complained of dryness in the mouth, but otherwise there were no complaints. The pains commenced to subside after the first few injections. The general condition and the weight improved and roentgenologic examinations revealed the gradual decrease in the size of the niche. Discussing the mode of action, the authors suggest that the sodium bromide inhibits the central nervous system and the irritations arising there and that the atropine acts on the terminations of the vagus nerve in the gastric and duodenal mucosa. This interrupts the vicious circle which is based on the instability of the sympathetic nervous system. The new conditions favor the cicatrization of the ulcer, which in turn diminishes the instability of the sympathetic. The authors conclude that this treatment represents progress in the conservative treatment of gastric ulcer.

- *Pneumococcal Peritonitis During Childhood Helene Mundorff—p 982

Cerebellar Atactic Form of Poliomyelitis—Glanzmann reviews the literature on the cerebellar atactic form of poliomyelitis and describes two cases. The onset is generally slow and the patients usually complain about fatigue in the legs and occasionally also in the arms. The weakness in the legs becomes so severe that the children are either unable to walk or, when attempting to do so, they stagger. The disorder may take its course without fever or with low fever. As the walk becomes more and more atactic, the children develop a tendency to fall toward one or the other side. A tendency to fall backward is comparatively rare. Analysis of the ataxia revealed in the author's cases the absence of Romberg's swaying, but in a case reported by Wieland this symptom was present. The finger-nose experiment often fails, in the knee-heel test, the child finds the knee only after long searching and in aiming movements post-pointing with hand and foot is observed. It is interesting that the signs of meningeal irritation which ordinarily are frequent in poliomyelitis seem to be entirely absent in the cerebellar atactic form. There is no rigidity of the neck, no spine sign and even Amoss's sign may be lacking. There are only indications of Kernig's sign and of the positive Lasegne sign. The four cardinal symptoms that are so important for the diagnosis of poliomyelitis fail completely in the cerebellar atactic form. Of especial interest is the lack of localized paralysis of the extremities. The musculature of the back and of the extremities show only a surprising lack of tonus and a more or less pronounced motor weakness. The cutaneous reflexes, particularly the abdominal and the cremasteric, are frequently increased, as are also occasionally the plantar reflexes. This increase in the cutaneous reflexes seems to indicate an irritation in the cerebral reflex arcs. The behavior of the tendon reflexes varies, they may be increased in both extremities or in only one and reduced or abolished in the other. In the two reported cases, the patellar and achilles tendon reflexes were abolished. The lumbar puncture reveals only a slight or no increase in pressure. The spinal fluid is clear, the Pandy reaction is positive and the Nonne reaction usually negative. As regards the clinical course, the author says that complete cure is the usual outcome. That this cerebellar atactic form is a form of poliomyelitis is proved by the fact that it occurs at the time of epidemics and that transitional forms exist. The author suspects that the process is localized in the brain stem and in the cerebellum.

Pneumococcal Peritonitis During Childhood—According to Mundorff, pneumococcal peritonitis still presents a much disputed problem, for the etiology, diagnosis, therapy and prognosis have not been completely clarified. At the children's clinic in Basel, thirty-three cases of pneumococcal peritonitis have been observed in forty years. In analyzing this material, the author found a predominance of children from rural districts. She says that this observation, as well as the fact that most of the patients were girls, has been made by several authors. The primary form of pneumococcal peritonitis has a sudden onset with diarrhea, high fever, small soft pulse, general unrest and dyspnea, that is, the aspects are almost those of a true toxemia. The local examination usually reveals sensitivity to pressure over the entire abdomen. The abdominal respiration is not so noticeably repressed as in appendicitis. Among the thirty-three cases there were seventeen with an acute onset and the aspects of a severe toxic process. The leukocyte count was high (between 16,000 and 34,000). Nine of the seventeen patients died. Death always followed within a few hours or, at the latest, three days after the intervention. In the other eight children recovery required from four to eight weeks and complications such as pneumonia, nephritis and late abscesses developed. The aspects of secondary pneumococcal peritonitis which develops in the course of other

pneumococcal infections, are quite different from those of the acute or primary form. In four of the sixteen children with the secondary form of pneumococcal peritonitis, the previous history revealed pneumonia. In the majority of the cases there developed within two or three weeks a generalized peritonitis, or, as happened in eight cases, a typical umbilical abscess, which on incision yielded a creamy pus that contained pneumococci. Five children died and eleven recovered. The hospitalization lasted from several weeks to five months. Of the complications, the pulmonary ones were the most frequent. In two instances rib resection had to be done on account of empyema. The author gained the impression that the secondary form of pneumococcal peritonitis has a more favorable prognosis than has the primary form.

Actinic Sterilization of Ovary—In experiments on adult rabbits, Momigliano found that a large dose of roentgen irradiation administered in a single treatment may fail to destroy the follicles, whereas it causes rapid and progressive atrophy of the ovary. Roentgen irradiations, administered in three or four fractional doses at intervals of a few days up to a total castrating dose, have a selective destructive action on primordial follicles without injuring the ovarian tissues, vessels and interstitial glands. When the intervals between irradiations are too short or too long, the biologic action of the irradiations diminishes. The influence of fractional doses in increasing or diminishing the biologic action of the rays depends on the rhythm of cellular proliferation after the irradiations, which is unknown. Primordial follicles, in evolution to maturity, are more sensitive to the biologic action of roentgen irradiation than immature and graafian follicles. Fractional repeated doses act by stimulating primordial follicles to maturity and arresting them in their further evolution. The treatment results in complete destruction of the follicular system with consequent permanent sterility of the ovary. In the clinical field the ideal is administering fractional doses chronologically during the phases of greater cellular proliferation of the ovary. Actinic castration will give better results than those obtained by irradiations with only a large dose, if a proper chronological rhythm in administering fractional doses is established.

Function of Liver During Anesthesia—Gagliardi studied the function of the liver in patients suffering from surgical diseases during anesthesia. The patients were placed in two groups—those with a normal liver and those who were suffering also from diseases of the liver or of the biliary tract. The studies were made by doing bengal rose tests and tests for bilirubinemia shortly before administration of anesthesia and fifteen or thirty minutes after beginning the operation. In some cases the tests were repeated two, four and eight days after the surgical intervention. The author concludes that in patients with a normal liver, anesthesia and the surgical trauma induce more or less intense but transient insufficiency of the liver. The intensity of the insufficiency depends on the type of anesthesia and on the more or less grave nature of the operation. In patients with latent or declared insufficiency of the liver, the latter is aggravated by the action of anesthesia and surgical trauma. The reticulo endothelial system of the liver is more sensitive than the other structures of the organ.

to the action of anesthesia and surgical trauma. The bengal rose test is extremely sensitive for showing liver insufficiency, especially if it is performed in association with the test of qualitative bilirubinemia.

Cultivation of Leishmania in Goat's Milk—Laurinsich made investigations on cultivating *Leishmania infantum* and *canis*. The culture mediums were prepared with pure goat or cow's milk alone or combined with rabbit's blood or the N N N culture medium. According to the author the cultural development of *Leishmania* greatly depends on the physical, chemical and constitutional conditions of the medium. Goat's milk, because of the amount of salts and dextrose that it contains and also its hydrogen ion concentration and stronger resistance against desiccation and aging than that of other culture mediums, is a favorable culture medium for *Leishmania*. The latter develops well in goat's milk, better if the milk contains hemoglobin and still better in mixed goat's milk and N N N culture mediums in which the organism develops exuberantly, lives longer than in any other culture medium and acquires a capacity of intense reproduction.

Skeletal Roentgen Changes in Congenital Hemolytic Jaundice—Acuña reports the cases of a group of children who were suffering from congenital hemolytic jaundice and who presented the same clinical symptoms. There was a high index of jaundice and a diminished globular resistance in all cases. An erythroblastic reaction and skeletal alterations of the type of those which are found in erythroblastic anemia were present in the minority of cases. The changes of the bones and the erythroblastic reaction were more intense in younger than in older children. Splenectomy resulted in disappearance of jaundice and improvement of the general condition of all the patients. However, the skeletal alterations and the erythroblastic reaction were not arrested by splenectomy. The author believes that the association of an erythroblastic reaction and skeletal alterations in congenital hemolytic jaundice shows a new form of hemolytic jaundice which is probably related to erythroblastic anemia. Three cases are reported.

Studies on Pneumothorax—Schill discusses the behavior of the mediastinum in case of pneumothorax, particularly in case of the formation of an exudate. He shows that after the formation of an exudate the mediastinum may become so rigid that it does not yield to pressure exerted either on the side of the seropneumothorax or on the contralateral side. In other cases the mediastinum remains flexible even after the formation of an exudate, probably because of the short duration. An

exudate is not the only factor that may cause mediastinal rigidity. Callosity of the pleura may develop in the absence of an exudate. The rigidity of the mediastinum, whether it has developed with or without the aid of an exudate, is of great significance in the collapse therapy of bilateral pulmonary tuberculosis, for in case of a rigid mediastinum the two lungs must be treated as separate entities. The degree of collapse must be regulated on both sides according to need, for it can not be expected that the pressure on one side will influence the other side, as is the case in the presence of a yielding mediastinum, when the collapse on one side produces automatically some collapse on the other side. The latter effect has an advantage in bilateral processes, but in unilateral tuberculosis it has a disadvantage in that the yielding mediastinum makes it difficult to obtain the desired degree of collapse on one side. On the basis of these observations the author stresses the importance of the measurement of the contralateral pressure during refilling of the pneumothorax.

Tuberculous Allergy—Hensel demonstrates that by treating guinea pigs with killed tubercle bacilli it is possible to produce a slight, rapidly disappearing tuberculin allergy. The specific allergy can be considerably increased and prolonged by using for the preliminary treatment killed tubercle bacilli together with hydrous wool fat and petrolatum. The allergy thus produced is to serve as a basis for further investigations on the allergy-immunity problem.

- *Some Observations on Relation of Carotene to Vitamin A in Human Blood Serum W Stepp and H Wendt—p 640

Carotene and Vitamin A in Human Blood Serum—Stepp and Wendt maintain that the body is not able to form vitamin A from inactive substances but has to rely for its supply on the intake of the vitamin in its final form or in the form of its provitamin, carotene. Human subjects and herbivorous animals are capable of transforming vegetable carotene to a considerable extent into vitamin A, whereas carnivorous animals have this capacity to a much smaller extent or not at all, the latter obtain their vitamin A in its completed form from meat. The blood serum of healthy persons contains both vitamin A and carotene. In case of an inadequate diet the vitamin A may not be demonstrable in the serum, but a complete absence of carotene was never observed in these rare cases. While the quantity of carotene and vitamin A in the serum fluctuates, the examination of a large number of healthy adults living on a mixed diet reveals a certain average value. The author measured the vitamin A content of the serum of healthy young men in Lovibond units (blue) and the carotene in Lovibond units (yellow). Although the two measures differ, the average ratio of carotene to vitamin A was as 26 to 1 in examinations that were made during July. When the same subjects were examined during October and November, the ratio of carotene to vitamin A had become greatly altered in that the carotene had increased much more than the vitamin A. It appears that, if large amounts of carotene are taken in the organism transforms only a part of it into vitamin A, whereas if only small amounts are consumed, it may transform the largest amount. In the latter event the vitamin A may even be present in larger amounts than the carotene. This seems to indicate that the organism has the tendency to maintain a certain level for vitamin A in the serum. The authors further discuss the relation between the carotene and vitamin A contents of the serum in the different age groups and in various pathologic conditions. They found that in the higher age groups the carotene content of the blood has a tendency to increase, the vitamin A to decrease. In hyperthyroidism the vitamin A requirements are increased and the values in the

blood normal In hypothyroidism, in myxedema, the transformation of carotene into vitamin A is impaired In acute hepatitis, normal as well as slightly increased values were observed, whereas in the more chronic hepatic disorders the carotene as well as the vitamin A values were greatly decreased In diabetes mellitus an increase in carotene as well as in vitamin A is the rule The authors admit that studies on larger materials will be necessary and stress that the determination of only one substance is insufficient for a proper estimation of the vitamin A metabolism

Tumors of Parathyroids and Osteitis Fibrosa Generalisata Cystica Recklinghausen Report of Three Cases Margarete Meisel—p 104

Formation of Diverticula in Appendix—Wunder describes the appendix that was removed from a man, aged 39, who had for some time vague pains in the abdomen, which gradually became localized in the right hypogastric region During the six months period that has elapsed since the operation the man has been free from complaints The examination of the appendix disclosed internal (intramural) as well as external false diverticula, then there were signs of chronic inflammation with scar formations in the musculature and, in addition to this, the musculature was interspersed with nodules consisting of connective and fatty tissues The cause and the time and course of development of this process could not be ascertained The congenital character could not be determined, because chronic inflammations were present, the previous acute stages of which also must have impaired the musculature

Infantile Form of Marble Bone Disease—Gerstel shows that marble bone disease can be differentiated into two groups In the first type, the infantile one, the disease progresses from the time of birth during the first months or years of life and leads to early death It is probable that this form begins in utero The second type of marble bone disease begins after puberty In this type the onset is more sudden It frequently begins with a spontaneous fracture The author describes the results of the pathologic-anatomic, histologic and chemical studies on a boy who during life presented the clinical aspects of marble bone disease with anemia The boy died at the age of 3 years and 9 months as the result of a secondary suppurating infection The author emphasizes that the disease of the bone, that is, of the static apparatus and its formative tissue, the epidiaphysal line, must be differentiated from the disease of the bone marrow and from the disease of the endosteum It should be remembered that, as regards origin and function, bone and bone marrow are entirely different In this connection it is pointed out that in some species of animals the bones do not contain marrow, hemopoiesis taking place in special glands The author shows further that the endosteum, which separates the true bone tissue from the bone marrow, is not merely a separating layer but is capable of rebuilding the bone Thus the bones combine a triad of tissues (1) the static apparatus or bone tissue in the strict sense of the word, (2) the separating and transforming endosteum and (3) the bone marrow The author further gives his attention to the question as to which apparatus is involved in case of marble bone disease On the basis of microscopic and chemical studies he denies that the so called marble bones are bones To be sure, there develop small areas of true bone, but they are insignificant in comparison with the marble masses The marble mass consists of two parts which differ in origin and remain separate the continuation of the cartilaginous matrix and the filling substance The essential disturbance in the course of ossification consists in toothlike projections of unused cartilaginous matrix into the diaphyses These projections prevent the formation of primitive trabeculae, so that the primary bone becomes globulated and grows as a filling mass down into the diaphyses Primary bone marrow is found at the border of the epidiaphyses, at which site there is no endosteum, that is, no cells which

effect rebuilding of the primary bone and the complete decomposition of the cartilaginous matrix On the outer surface of all bones brownish deposits are found which in their microscopic aspects resemble brown tumors and in which rebuilding of bone takes place The periosteum is not involved in this process

*Treatment of Phthisic Night Sweats by Combination of Hypnotics Influencing Brain Stem and Cerebral Cortex A Hofmann—p 1355

Vitamin A in Pneumonia—In view of the limited knowledge on the vitamin A content during infectious diseases, Lindqvist investigated the vitamin A content of the serum of forty-five patients with pneumonia He extracted the carotinoids and the vitamin A from the serum by the method recommended by van Eekelen and Emmerie He observed that the carotinoid and vitamin A content was low during the course of the pneumonia A tabular report indicates that in all but six of the patients the values were below the normal average These low values exist during the first few days of the pneumonia, During the convalescence the values increase rapidly without vitamin A being added to the diet One week after the crisis the vitamin content is usually three times as high as before the decrease in temperature There is no storage of vitamin A in the diseased lung The cholesterol content of the serum is considerably decreased, but this is not responsible for the disturbances in the vitamin A content During the fever period, large quantities of vitamin A are eliminated in the urine The vitamin A content of the liver is in most cases considerably reduced, but there are also cases in which the values are high The author thinks that under pathologic conditions the vitamin A content of the serum is not a reliable measure for the vitamin standards of the organism The low vitamin A content of the serum of patients with pneumonia is partly the result of excessive elimination in the urine Moreover, the mobilization of the hepatic stores may be difficult It was impossible to determine to what extent a low vitamin content was present before the development of the pneumonia

Treatment of Phthisic Night Sweats—Hofmann cites factors and investigations which prove that the secretion of sweat is influenced by the cerebral cortex In the treatment, however, this influence is usually disregarded The author decided to try a central modification of sweats, particularly the central suppression of the sweats of phthisic patients Tuberculous patients, who are subject to profuse night sweats, generally say that their sleep is restless and superficial If they are given an ordinary hypnotic (barbital), that is, one which influences the brain stem, the results are quite favorable However, it should be understood that the patient is not merely prevented from noticing the sweating by his deeper sleep, he actually does perspire less The results are even better if the hypnotic influencing the brain stem is combined with one which influences the cerebral cortex (sodium bromide) The author recommends the combined administration of these two types of hypnotics

*Value of Some Diagnostic Procedures in Diseases of Peripheral Arteries A von Razgha—p 1054
Remarks on New Means of Obliteration of Varicose Veins S Szandicz—p 1057

Diagnostic Methods in Diseases of Peripheral Arteries—According to von Razgha oscillometry and the determination of the cutaneous temperature are the two methods that are used most frequently in the diagnosis of the disorders of the peripheral arteries In some countries oscillography is used

more widely and in others the determination of the cutaneous temperature. The author employed both methods. He shows that for the correct estimation of the oscillometric values it is necessary to consider the factors that influence the form and size of the oscillations. Although sclerotic or spastic narrowing of the vessels may reduce an otherwise normal pulse wave, smaller oscillations do not always signify local vascular changes, for a decompensated cardiac defect may likewise cause a reduction in the pulsatory filling of the vessels. In the presence of certain cardiac defects the local diagnostic value of oscillometry is therefore limited. Further the author shows that, if oscillometry reveals subnormal values, it has to be decided whether the causal factor is an organic or a spastic condition. The latter can be overcome by vasodilatory measures such as a local warm bath and by spasmolytic medicaments. The author compared the effect of an intravenously administered spasmolytic and of a hot bath in twenty-four patients with low oscillatory values. In some patients the two measures had the same effect, in others the intravenous injection proved more effective than the warm bath. Extremely severe vascular spasms may not completely yield to the combined application of the two methods, nevertheless they always effect some dilatation and serial examinations will clarify the spastic character. If oscillometry indicates an organic lesion, the clinical aspects will usually help to decide whether Buerger's disease, a specific arteritis, arteriosclerosis, embolism, thrombosis or aneurysm exists. In discussing the determination of the cutaneous temperature, the author stresses that it is influenced by several external factors and that a comparison of results is justified only if the measurements have been made under the same conditions. In cases of an asymmetry of the temperature between the two sides, oscillometric control tests were made. On the whole, the author gained the impression that the simple determination of the cutaneous temperature is of only slight value and that the oscillometric procedure gives a better insight into the peripheral vascular disturbances.

Food Poisoning by Bacillus Botulinus Type B. A. Clarenburg and J. N. Fijen—p. 4806

Treatment of Schizophrenia with Insulin and Metrazol—At Kastein's clinic, a number of schizophrenic patients were subjected to the combination treatment with insulin and metrazol. It was found that, if metrazol is administered during the insulin coma, an epileptic attack can be elicited with half the dose that would be required under normal metabolic conditions. After the epileptic attack that has been elicited by metrazol, the depth of the insulin coma is decreased so that the patient can answer questions and is able to eat alone. Moreover, the blood sugar rises after the injection of metrazol, this increase is greater when the injection is followed by an epileptic attack. Experiments on rabbits confirm these observations on the relation between insulin and metrazol, namely, that the two substances are synergistic as regards the elicitation of the epileptic attack but antagonistic in their effect on the level of the blood sugar.

Postmortem Examination of Coronary Vessels—Nieuwenhuizen and de Waard point out that the development and extension of muscular infarction is determined not only by local changes in the wall of the coronary arteries but also by dynamic factors (collateral blood supply, condition of venous drainage). Therefore changes in the electrocardiogram must be evaluated with care for they are not necessarily caused by anatomic changes in the coronary arteries and in the cardiac muscle. The authors show that the postmortem roentgenologic examination of the coronary system before and after filling with a contrast medium is a valuable aid in throwing light on these problems. They describe observations in five cases. They found that coronary thrombosis may be absent in cases of severe calcification and tension, whereas it may be found in the presence of a moderate degree of calcification and narrowing. Moreover, there is evidence that the clinical aspects of

coronary thrombosis may be produced by acute coronary insufficiency without infarction. Finally the authors describe an infarct that was observed in a patient with a dissecting aneurysm of the aorta. In this patient the sinus venosus was obliterated by the pressure of the aneurysm, this produced stasis in the venous drainage and the latter, together with the insufficient blood supply caused by calcification and the narrowing of the descending branch of the left coronary artery, caused a stasis infarct.

*Investigations in Illumination of Intoxication Theory in Dementia Praecox with Especial Reference to Attempts at Total Transfusion. P. J. Reiter—p. 287

Bacteriologic Epidemiologic Experiences Concerning Infections with Gastro Enteritis Bacilli of Paratyphoid Group. Ctd. M. Kristensen, K. Boylen and C. Faarup—p. 310

"Total Transfusion" in Dementia Praecox—By "total transfusion" Reiter means emptying most of the patient's blood at one session and introducing an equal amount from a number of donors. There are many practical obstacles—the requirement of preferably nine donors of the patient's type for each experiment, a correct diagnosis, an active process as far as can be established, the patient's physical condition and consent of the patient's family to the intervention. Attempts at detoxication of grave schizophrenic processes by "total transfusion" have during four years been possible in only four cases, one of paranoid dementia, one of hebephrenia and two of catatonia. No donors were from among the patients' relatives. The results seem to the author to indicate that at least in a considerable number of cases of schizophrenia the intoxication theory is probably correct, he says that the clarification in the second case to a marked degree upholds the theory, which is also supported by the results in the first and third cases. In the fourth case, in which the psychosis was resistant to the "total transfusion," there was marked reaction of the white blood corpuscles in the direction of proliferation of immature cell forms. When careful preparations are made and the operation is performed with the necessary technical skill, "total transfusion" in itself is regarded as apparently relatively safe.

*Changes in Serum Proteins in Patients with Venereal Lymphogranuloma (Nicholas Favre) and Genito-Anorectal Syndrome (O. Jersild). N. Jersild—p. 1059

Dextrose Studies. II. M. Nørn—p. 1069

Changes in Serum Proteins in Venereal Lymphogranuloma—Jersild examined fifty-five serums, the number of cases of venereal lymphogranuloma in Denmark being limited. He states that hyperproteinemia, increased sedimentation, a positive formol-gel reaction and a positive Takata reaction frequently appear in connection with venereal lymphogranuloma and rectal stricture when the infection is active (acute or chronic). In 86 per cent of the acute cases the relative globulin percentage was more than 40, in 53 per cent there was positive formol-gel reaction, in 55 per cent a positive Takata reaction. In 96 per cent of the chronic cases the relative globulin was more than 40, in 92 per cent there was positive formol-gel reaction and in 92 per cent a positive Takata reaction. When only a positive Frei reaction testified to an ended venereal lymphogranuloma infection, corresponding shifts in the serum were not found. Of 10,000 serums sent to the State Serum Institute, only twenty, or 2 per cent, showed a positive formol-gel reaction in less than three hours, of these two were from patients with rectal stricture, one from a patient with a disorder possibly due to an earlier venereal lymphogranuloma. Since protein changes in the serum are rare in Denmark a certain significance must be attached to them in the diagnosis of venereal lymphogranuloma. The changes in the serum proteins in venereal lymphogranuloma are perhaps an expression of a disorder in the reticulo-endothelial system. From the presence of abundant plasma cells in the affected tissue in venereal lymphogranuloma and other disturbances with hyperglobulinemia (multiple myelomas, kala-azar), this cell form presumably in some way plays a part in the serum changes, whether it occurs in the reticulo-endothelial system or on the side of the bone marrow.

AMENORRHEA ITS CAUSATION AND TREATMENT

ROBERT T FRANK, MD
MORRIS A GOLDBERGER, MD
U J SALMON, MD
AND
GERTRUDE FELSHIN, MD
NEW YORK

This investigation of patients with amenorrhea is a continuation of our studies on oligomenorrhea, amenorrhea and sterility begun in 1931¹. Since our last publications the methods for determining the gonadotropic factors in both blood and urine have been improved². As far as treatment is concerned, pure estrogenic substances are now available in large dosage. In addition to gonadotropic substances from pregnancy urine or the placenta, which lack some of the properties of the adenohypophysis, physiologically potent gland preparations and their equivalent—the serum of pregnant mares—are now available. This permits a better evaluation of any prepituitary effects that might be obtained in our carefully controlled series of cases.

MATERIAL

The patients selected had suffered with amenorrhea for various periods and were of various ages. Intelligence, faithful carrying out of orders, ability and willingness to report as directed were of importance in the choice. In one instance the investigation covered 430 days. In only five cases were the studies continued for less than one entire month.

The total number of cases studied was twenty-seven. Of these, six were primary in which menstruation had never occurred and twenty-one secondary amenorrheas. The ages of the patients and the duration of amenorrhea are given in table 1.

CLINICAL CRITERIA

By all available clinical criteria determined as a routine before selecting the patient, including the secondary sex characters, basal metabolism, blood examinations, sellar x-ray films, Janney test for sugar

tolerance, blood pressure, pelvic examination, and the like, twenty-four of the twenty-seven patients showed no serious deviations from any group of normal women of similar economic and social status. Included are private patients, housewives of all strata and single women of the leisure and working classes. In the great majority the sole complaint was the amenorrhea. A few complained of flushes,³ others of breast engorgement, a few of unrelated, mainly nervous, symptoms. The three other patients had hirsuties and two of these large clitorides.

LABORATORY STUDIES

Complete estrogenic determinations, extending at least over one month, were made on twenty-one patients. In several, these determinations were repeated. In ten, both estrogenic and gonadotropic determinations were made, including weekly blood specimens for the determination of both the estrogenic and the gonadotropic factors, as well as continuous urine examinations over thirty days of estrogenic and gonadotropic factors. In six, only estrogenic and gonadotropic blood determinations were made. In six, gonadotropic urine determinations were performed.

Our purpose in the laboratory study was to see how these women differed with regard to their hormones from the many norms previously determined by the same methods. Chart 1 shows the normal, fertile, menstruating woman. Another important graph to contrast with the group investigated is the one obtained from castrated or spontaneous menopause (chart 2).

In a previous paper from this laboratory^{1a} we classified amenorrheas into three groups, based mainly on the estrogenic assay. In the first group the blood curve showed a considerable diminution in the premenstrual rise, though occasionally an entirely normal graph was obtained. In a second group the blood was negative and the estrogenic excretion in the urine diminished. The third group was acyclic, neither blood nor urine showed more than a trace of estrogens. In the present investigation complete gonadotropic studies were simultaneously performed in similar groups of cases.

ESTROGENIC STUDIES

Twenty-one cases are available in which complete estrogenic examination of urine over one month was made. These have been subdivided into four groups.

(a) *Low (Acyclic)* (from 50 to 200 mouse units) — Of these, three cases were primary and four were secondary amenorrheas of from four to seven years' duration. In all of them the blood studies showed no estrogenic reaction in 40 cc of blood. The gonadotropic factor in the blood was high in two and negative in one. The gonadotropic factor appeared in the urine

3 The neurovascular symptoms usually associated with the menopause (flushes, sweats and the like) occur also not infrequently in normally menstruating young women of nervous temperament.

in very small quantities in 1 It was not determined in six This group, whose ages varied between 20 and 33 years, corresponds closely to the acyclic group, described in our previous studies (chart 3)

(b) *Subthreshold Estrogenic Urine Content* (from 500 to 850 mouse units) —There were five cases in this group in which from 565 to 850 mouse units of estrogenic substance was excreted during one month

Chart 1—Gonadotropic and estrogenic hormones in the blood and urine cycle of a normal menstruating woman The explanation of the stippling and shading used in the charts is given in chart 2

Of these, two were primary and three were secondary amenorrheas, the durations being from two to nine years The patient who was amenorrheic for nine years had had two children before the onset of the amenorrhea

Of this group in two cases a blood reaction of plus 4 was demonstrated once during thirty days (see normal,

Chart 2—Total urine estrogenic output 637 mouse units in a woman aged 32 surgically castrated two months previously

chart 1) and both of these cases showed one rise of gonadotropic substance in the blood One of the five patients had a specimen showing gonadotropic substance in the urine and one other showed evidence of some accumulation in the blood

As a group these correspond to our subthreshold group of the previous investigations with some indication of a cycle The total monthly excretion of

estrogenic substance was equal to from one fourth to one half of the estrogenic substance found in a normal woman (chart 4)

(c) *Normal Estrogen Excretion* (from 1,000 to 1,714 mouse units) —In this group there were six cases, one primary and five secondary amenorrheas, with a duration of from one to seven years One of these patients had presumably aborted at an early stage four years previously

Two of the patients had a normal accumulation of estrogen in the blood, two showed a subthreshold accumulation, and two showed no cyclic estrogen in the blood Five of these cases were studied also for gonadotropic substance in the blood A reaction was obtained in two, one with a real increase Gonadotropic examination of the urine was made in only three cases, one being positive

An analysis of this group favors a disturbance of the cycle rather than evidence of low ovarian activity (charts 5 and 6)

(d) *Excessive Estrogenic Excretion* (from 2,075 to 2,328 mouse units) —There were three cases in this group, one primary and two secondary amenorrheas

2	33 years

of short duration—five and nine months respectively All three showed accumulation of estrogenic blood and one of these patients who had not menstruated for five months menstruated spontaneously ten days after the termination of the study This group falls into the type described by Zondek⁴ as the polyhormone group They appear to be much rarer in our series than was noted by Zondek (chart 7)

The quantity of estrogenic substance excreted in the urine is important in diagnosis and prognosis, and it has likewise been of use in evaluating the effects produced by various forms of therapy, as will be discussed later in this article Moreover, it has emphasized the importance of insisting on a continuous month's study because, in several instances, repeated specimens are consistently negative over from nine to twelve days and then considerable amounts, as much as from 400 to 600 mouse units, are excreted in the course of the next succeeding days Whether this sudden excretion corresponds to follicle ripening (or ovulation) and to the premenstrual increase of excretion must as yet remain unanswered (chart 8)

⁴ Zondek Bernhard Hormone des Ovariums und des Hypophysen-vorderlappens ed 2 Vienna Julius Springer 1935

That ovulation may occur during amenorrhea is proved by the following cases

A woman, aged 23, with primary amenorrhea, was observed by one of us recently. Although she had never menstruated and was without molimina, she conceived and required operation for ectopic gestation.

A woman, aged 33, a secundipara, whose last child was 7 years old, had been amenorrheic for fourteen months. When seen, the uterus was the size of a six weeks pregnancy, the Friedman test was positive, she carried through to term.

COMMENT ON ESTROGENIC EXCRETION

The low groups, namely, those with excretion of from 50 to 200 mouse units and from 500 to 850 mouse units in the course of thirty days, must be regarded as having diminished ovarian function. The increase of gonadotropic substance in both of these groups was not sufficiently distinctive to bespeak such diminution in ovarian function as may follow preponderance of the prepituitary activity similar to that which takes place in the menopause, nor, as will be referred to later, was the response to estrogenic therapy in these patients the same as in women in the menopause.

The third group, in which the estrogenic excretion was from 1,000 to 1,714 mouse units in a month,

Chart 3—Primary amenorrhea in a single woman aged 23. The total estrogenic output in the urine was 136 mouse units.

parallels sufficiently closely the normal amount of excretion (from 1,300 to 1,700 mouse units in a cycle) to warrant the presumption that an approximately normal amount of ovarian activity was evidenced. Four of this group in addition showed a cyclic blood accumulation of estrogenic substances.

Consequently we conclude that some as yet unanalyzable disturbance in the cycle rather than merely low ovarian activity must at times be at fault. The gonadotropic studies did not help in clarifying or in showing that the pituitary is the primary factor, as seems most likely on theoretical grounds.

The last group with excessive estrogenic excretion (from 2,075 to 2,328 mouse units), all of whom had blood accumulation at one time of the study, are particularly puzzling. The sole explanation that we are willing to offer even tentatively is that ovarian overfunction might disturb the cycle analogously to the continuous absence of bleeding, which follows the administration of large amounts of estrogen to castrated

primates, not until the injections are stopped does menstruation occur. In one of the cases in this group, menstruation occurred spontaneously shortly after the completion of the study, but this has also happened in patients of the lower groups in our previously published studies. Whether the foregoing is the full and sole explanation is still to be decided.

Chart 4—Primary amenorrhea in a single woman aged 23. The total estrogenic output in the urine was 851 mouse units.

Numerous and repeated assays performed with crystalline ketohydroxyestrin on large groups of castrated mice from our colony at various times during the course of the study show that our mouse unit lies between 0.8 and 0.9 microgram (the international unit equals 1 microgram).

GONADOTROPIC STUDIES

In the gonadotropic studies of the blood and urine, in which the follicle stimulating and lutemizing effect on immature rats was assayed, two groups were noted. In the one continuous and excessive secretion and excretion were observed, in the other the gonadotropic factors were found absent throughout.

Chart 5—Secondary amenorrhea in a woman aged 34 married five years with no pregnancies, whose last menstrual period was three years before. The total estrogenic output in the urine was 1,166 mouse units.

High and Continuous Gonadotropic Excretion (four cases, all of secondary amenorrhea).—All these patients showed continuous and persistent gonadotropic excretion. One was observed at frequent intervals for more than one year (chart 9). The daily amounts

7. Allen Edgar. Further Experiments with an Ovarian Hormone in the Ovariectomized Adult Monkey, *Macacus Rhesus*. Especially the Degenerative Phase of the Experimental Menstrual Cycle. *Am J Anat.* 42: 467 (Nov.) 1928.

8. Marrian (Cohen, S. L., Marrian, G. F. and Odell, A. D.). Oestrial Glucuronide. *Biochem. J.* 30: 2250 (Dec.) 1936. Has raised the question of whether a difference in physiologic phenomena may result depending on whether the excreted estrogens are free or combined (glucuronic esters). His studies were limited to pregnant patients. In an as yet unreported series of normal women as well as in our amenorrheic patients less than 1 per cent of the free estrogenic factor was found.

averaged from 5 to 10 rat units. This differs markedly from the normal menstruating woman and resembles hormone conditions of the menopause (chart 2).

The estrogenic study of these patients showed, and this appears to be a fortunate accident, that they fall into one of each of the previously described categories, their monthly excretion of estrogens having been found to be respectively 75, 565, 1,166 and 2,328 mouse units.

Chart 6—Secondary amenorrhea in a woman aged 26 married four years with one pregnancy (aborted four years before) the last menstrual period was four years before. Total estrogenic output in the urine was 1,415 mouse units.

Absent Gonadotropic Excretion (six cases, four primary, two secondary)—Theoretically these would conform more closely to the accepted concept of amenorrhea, namely, diminished gonadotropic function and consequent afuction of the ovaries, were it not for the fact that one of this group excreted large amounts of estrogen and two approximately normal quantities. The amount of estrogenic substance excreted by these cases is given in table 2.

Just as an analysis of the estrogenic factor fails to offer a complete explanation of amenorrhea, the same holds true of the gonadotropic study. In immature animals, injection of sufficient amounts of gonadotropic factors (A. P. L.—anterior pituitary extract from placenta [Collip], extract of pregnant mares' serum

TABLE 2—Estrogenic Substance Excreted

Low	{ 115 M U 136 M U	Normal	{ 1064 M U 1714 M U
Medium	{ 841 M U 910 M U	High	2185 M U

[Upjohn], or extract of the pituitary gland [Parke, Davis]) produces follicle stimulation, ovulation and luteinization with the well known correlated changes in the uterus. Whether the presence of the adult ovary can interfere with this reaction has not been established. That the adult rodent ovary can be forced to react to these stimuli, even in pregnancy, is shown when pregnant rabbits are injected with pregnancy urine.⁹

Our studies show that both when the gonadotropic factor is in excess and when it is deficient, estrogenic secretion can be diminished, normal or excessive. The two clinical cases previously described demonstrate that ovulation and impregnation may take place during amenorrhea. May not some other temporary, uterine retractormess to bleeding be at fault?

⁹ New manner of injecting in addition to the corpora lutea already present.

THERAPY

Use of Estrogenic Substances—Seven of the cases studied and referred to in previous paragraphs were selected for estrogenic therapy. The estrogens were given in the form of progynon-B (estradiol benzoate hypodermically, or progynon-DH (estradiol) by mouth.⁹

The dosage of estrogens given varied between 16,000 rat units (corresponding to 80,000 international units) and 690,000 rat units (corresponding to 3,450,000 international units) as total dosages. From these studies it is evident that primary and secondary amenorrheas respond or fail to react approximately in the same fashion. It soon appeared that amenorrheas react entirely differently to the estrogenic substances than do patients in the menopause who respond irrespective as to whether the menopause is spontaneous or is due to surgical castration or to x-ray castration. The menopause group shows not only a rapid disappearance of excessive gonadotropic substance from the circulation and the urinary excretion but also rapid disappearance of the symptoms. No effect whatever was noted in the amenorrhea groups between the dosage of 16,000 and 135,000 rat units with one exception, not investigated as to hormones.

This is in sharp contrast with three private patients of the senior author who, to alleviate menopause symptoms, took progynon-DH (1,800 "active biological units" [27 mg.] daily) continuously for several months (this included two patients with spontaneous menopause and one woman, aged 40, who was castrated by means of x-rays). From four to six days after stopping medication, these women were surprised and alarmed by the appearance of profuse uterine bleeding, which did not recur.

In our studies we found that at least 200,000 rat units (1 million international units) were necessary to reduce the excessive excretion of gonadotropic hor-

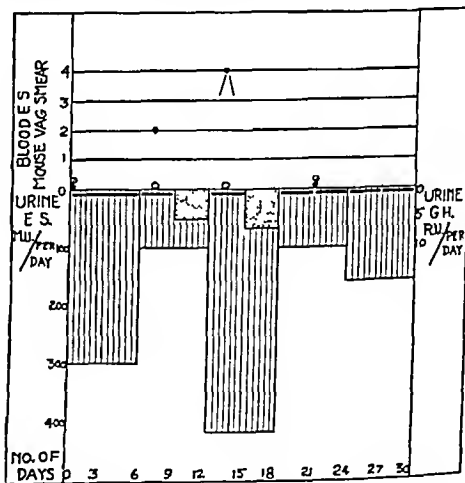

Chart 7—Primary amenorrhea in a woman aged 30 married 16 years with no pregnancies. The total estrogenic output in the urine was 2185 mouse units.

none, while in one case 400,000 rat units failed to produce this change. Artificial menstruation occurred in only two cases, in the one with 600,000 and in the other with 200,000 rat units. One patient who received 690,000 rat units, another 400,000 rat units, showed no

⁹ Drs. Gregory Stragnell and Erwin Schwenk of the Schering Corporation of Bloomfield, N. J. extended many courtesies and supplied large quantities of material used in these and other experiments.

response of any kind. One who received 400,000 rat units and another 135,000 rat units spotted slightly for a few days. In the few instances in which uterine suction biopsies were performed, slight interval activation of the endometrium could be noted.

Chart 9 shows strikingly the huge amounts of estrogen necessary to reduce gonadotropic overexcretion. This patient was studied with short intervals of rest for more than one year.

Chart 8—Secondary amenorrhea in a woman, aged 33, married eleven years, with two children the last seven years ago. The last menstrual period occurred four years ago. Total estrogenic output 565 mouse units in two periods of excretion with intervals of fifteen and nine days without estrogenic excretion. Gonadotropic excretion continuous.

The effects obtained differ to a considerable extent from those reported in the literature.¹⁰ We must emphasize particularly that no evidence of periodicity developed in our cases even when such courses of treatment as those described were repeated at intervals. This is not at all surprising when the slight effect on the excessive gonadotropic secretion and excretion, if present, produced by huge doses is taken into account.

The sole exception is a private patient of one of us (U. J. S.) not studied with regard to hormones, in whom periodic and descending doses of estrogen (progynon B, hypodermically) produced menstruation.

This woman, aged 24, weighing 240 pounds (109 Kg.), and who never dieted, with a basal metabolic rate of 2 per cent, hirsute, never gravid amenorrheic for fourteen months, was observed for more than 320 days. As can be seen from chart 10, 247,000, 50,000, 82,000 and 32,000 rat units were injected. Each injection was followed by bleeding. She bled for three days spontaneously after the elapse of sixty-five days but has not bled since then (fifty-six days).

Use of Gonadotropic Substances.—Four cases of both primary and secondary amenorrhea were tested at varying intervals, with different dosages of concentrated pregnant mare serum, containing gonadotropic substances.¹¹ Both primary and secondary amenorrheas were included in this group. The dosages given, according to Upjohn Company units, were from 60 to 510 rat units. Each Upjohn unit corresponds to at least 3 of our units as determined by us on our immature rats. Our unit is based on the minimum dose which produces ovarian luteinization. In no instance did menstruation follow the treatments.¹² No periodicity could be obtained by giving various doses at intervals of two or four weeks.

10 Mazer Charles and Irael S. L. Studies on the Optimal Dosage of Estrogens. An Experimental and Clinical Evaluation. J. A. M. A. 108: 163 (Jan. 16) 1937.

11 Dr. Cartland of the Upjohn Company, Kalamazoo, Mich., supplied us with the tablets containing the gonadotropic substances used in these experiments. They were prepared solely for experimental trial.

12 Before using this gonadotropic concentrate each patient was tested for sensitivity to horse serum. In none of those treated was an allergic response noted but without this precaution serious consequences might arise.

The use of unfractionated anterior pituitary extract (antuitrin)¹³ prepared from animal pituitaries proved equally ineffective.

We are, of course, well aware that gonadotropic preparations are as yet not sufficiently purified and concentrated to warrant drawing final conclusions as to their efficacy.

Nonspecific Treatment.—From these disappointing results it would appear that both primary and secondary amenorrheas, for which no causation could be discovered, react quite differently from the large group of amenorrheas seen in our endocrine clinic which follow the development of obesity, malnutrition or thyroid deficiency.

Obesity. In this group we have patients whose weight reaches to 300 or more pounds (136 Kg.). The basal metabolism of these patients is studied (the majority prove normal), the sella turcica is roentgenographed to exclude pituitary tumor, and a sugar tolerance test and other tests are made. Examinations, with the fewest exceptions, are negative. When such patients are put on a low caloric diet by cutting down carbohydrate and fats and being given sufficient protein, until the weight has been reduced, menstruation regularly supervenes and continues.

Malnutrition. Another group, almost as numerous since the economic depression, are the adolescents whose home surroundings prevent them from obtaining adequate nourishment. As soon as these patients, with the aid of social agencies, are given a liberal nutritious diet, fresh air and better surroundings, their menstruation likewise returns and becomes normal.

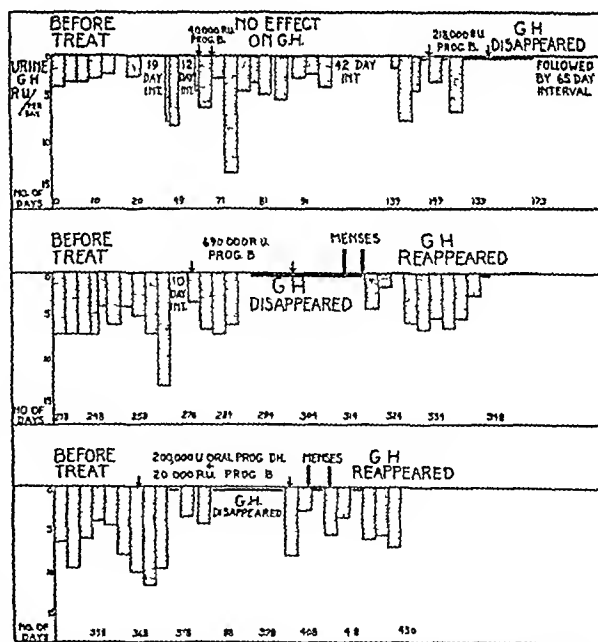

Chart 9—Secondary amenorrhea in a woman aged 20 single whose last menstrual period occurred four years before. Study of gonadotropic hormones.

A very interesting group is that of voluntary starvation, sometimes called "anorexia nervosa" of which we have observed three instances. The diagnosis previously made on all of these patients had been Simmonds' disease. They were all young adults and in every case resentment against parents and "too much

13 The Research Laboratories of Parke, Davis & Co. supplied this preparation.

family" caused the loss of appetite and increasing refusal of food. One of these women was submitted to a month's study of blood and urine and fell under the heading of "low excretion" of estrogen. These patients required nothing but hospitalization for several weeks, with complete separation from their families, to overcome the psychic factor, and all three rapidly regained full health with return and persistence of normal menstruation.

Thyroid Deficiency Thyroid deficiency in some patients, as previously described,¹⁴ is sometimes, particularly in the puberty group, followed by menorrhagia. In the majority of cases, however, amenorrhea supervenes. The nutrition of these patients is usually normal. Their basal metabolic rate is found to be between —20 and —35 per cent. The amenorrhea is of variable duration. The response to appropriate thyroid medication by mouth is startlingly uniform and successful. Usually thyroid substitution must be continued indefinitely.

Spontaneous Return of Menstruation—Final and convincing analysis of the factors causing amenorrhea is made still more difficult by the not infrequent spontaneous reappearance of normal menstruation without treatment. One such case (polyhormonal) was observed at the termination of the month's study. Previously

Chart 10—Secondary amenorrhea in a woman of 24, of fourteen months duration, weight 240 pounds (109 Kg). This patient menstruated after decreasing doses of estrogenic substances were given at intervals.

we have encountered seven such cases, in which, during or following the blood study, the amenorrhea disappeared. In all these increase of blood estrogen to plus 4 as in the normal (chart 1) was noted (previous amenorrhea from two to seven years). One patient had remained amenorrheic and sterile for seventeen years. She then menstruated and bore two children.

In this connection no mention has been made of amenorrhea developing during the course of serious and diagnosticable endocrine disease such as pituitary tumor, Addison's disease and adrenal cortical carcinoma. Such cases will be discussed in another article. The patients described in this study all fall into the group of functional disturbances.

SUMMARY

1 Of twenty-seven amenorrheic patients investigated, both primary and secondary, five were studied for less than one month, the remainder for from one month to more than one year.

2 The ages varied from 20 to 37 years. Of the eighteen married patients sixteen were sterile.

3 The amenorrhea had existed for from five months to nine years in the secondary group, the primary group (six patients) were from 23 to 33 years of age.

4 Twenty-four of the patients showed no endocrine stigmas, three had hirsuties and of these two had enlarged clitorides.

5 In twenty-one cases complete studies of the urinary excretion of estrogens were performed for more than one month. The patients fall into four groups.

(a) *Low* from 50 to 100 mouse units total monthly excretion. There was no positive estrogenic reaction in 40 cc of blood in any. Seven cases.

(b) *Subthreshold* from 500 to 518 mouse units excretion, two showed estrogen in blood. Five cases.

(c) *Normal Excretion* from 1,000 to 1,714 mouse units. Four showed some estrogen in blood. Six cases.

(d) *Excessive Excretion* from 2,075 to 2,328 mouse units. All showed estrogen in blood. In our series this group (Zondek's "polyhormonal amenorrhea") is less numerous than anticipated.

6 In ten cases complete studies of the urinary excretion of gonadotropic substances were performed for one month or more. These patients fall into two groups.

(a) *High and Continuous Gonadotropic Excretion*—Four cases. All four estrogenic groups were represented (see 5 a, b, c, d).

(b) *Absent Gonadotropic Excretion*—Six cases. Again all four estrogenic groups were represented.

The gonadotropic blood and urine studies cannot be correlated to the estrogenic conditions, thus differing both from normal women in whom the blood and urine show preovulatory accumulation and from patients in the menopause in whom blood and urine show continuous and increased amount of gonadogens.

7 The doses of estrogen given for therapeutic effect to amenorrheic patients varied between 16,000 and 690,000 rat units (80,000 and 3,450,000 international units). Below 200,000 rat units no response obtained. Even with the large doses employed a single uterine bleeding followed in only two and scant spotting in two. Approximately one tenth of the estrogen given is excreted in the urine.

8 Gonadotropic substances (extract of pregnant mare's serum, anterior pituitary gland extract) in dosage of from 60 to 510 rat units produced no effect.

9 In contrast to the foregoing groups were patients afflicted with obesity, malnutrition and hypothyroidism, who uniformly responded to appropriate therapy.

10 Finally, attention is drawn to the considerable number of patients in whom menstruation returns with out any treatment or ascertainable cause.

CONCLUSIONS

In amenorrheic women a wide variation in the hormone status occurs.

Evidence of almost complete ovarian afuction, subthreshold function and normal follicular activity as well as excessive activity are represented.

In these four groups the gonadotropic assay may show either overfunction or underfunction.

No evidence pointing to either a primary pituitary or a primary ovarian causation of amenorrhea could be demonstrated.

Amenorrhea does not preclude the occurrence of ovulation or pregnancy.

The response to estrogenic therapy of amenorrheic patients differs markedly from that in the menopause.

The threshold of response in amenorrhea is far higher than in the menopause.

This difference can be utilized in patients to differentiate between the two conditions, if an excess of gonadotropic substance has been found in the urine. Disappearance of gonadotropic substance produced by 30,000 rat units of estrogenic substance warrants the diagnosis of menopause.

No useful purpose is served in prescribing estrogens for the treatment of amenorrhea.

In the dosage used by us, gonadotropic preparations likewise proved ineffective.

It is justifiable to try very high dosage of gonadotropic preparations when these become available.

Our study has failed to locate the cause or causes producing amenorrhea.

Not only ovarian or anterior pituitary refractormess but also a failure of uterine response must be considered in the etiology.

THE TREATMENT OF MENORRHAGIA AND METRORRHAGIA BY ENDOCRINE PRODUCTS

JOHN C BURCH, MD
G S McCLELLAN, MD
JOHN W SIMPSON, MD
CLAUD D JOHNSON, MD
AND
E T ELLISON, MD
NASHVILLE, TENN

Menorrhagia and metrorrhagia are among the most interesting complaints confronting the gynecologist. They result from a variety of both organic and functional diseases. In the latter, endocrine products are useful, in the former, they have no place. In any discussion of the treatment of abnormal uterine bleeding, one must remember that bleeding is only a symptom and that it can result from various causes. An adequate diagnosis is a prerequisite to rational therapy. It is our purpose in this paper to present certain observations concerning the etiology of functional uterine bleeding and the rôle of endocrine products in the treatment of menorrhagia and metrorrhagia.

Two lines of study have contributed to this progress. On the one hand, a combination of clinical and pathologic observations has established the relationship of the symptoms to the microscopic appearance of the endometrium. On the other hand, the experimental reproduction of the endometrial changes has enabled us to obtain information concerning the relationship of these symptoms to the organism as a whole.

The most striking form of functional menorrhagia and metrorrhagia is found in association with glandular cystic hyperplasia of the endometrium, and studies of this condition have led to an understanding of the disorders of menstrual interval and flow.

Schroeder¹ was the first to emphasize the correlation between endometrial hyperplasia and ovarian changes characterized by the absence of the corpus luteum and the presence of follicle cysts. These observations have been repeatedly confirmed by others. However, only

after the ovary had been shown to elaborate the specific substances estrogen² and progesterone³ was it possible to attack the hyperplasia problem by experimental means. Castrated rodents,⁴ monkeys⁵ and human beings⁶ were injected with estrogenic substances over long periods of time, and in all cases the typical histology of glandular cystic hyperplasia was produced.

Since partial castration in rodents had previously been shown to produce a disordered estrous cycle,⁷ and since the ovarian studies by Schroeder¹ and others⁸ indicated a deficiency of ovarian function, it seemed probable that endometrial hyperplasia could be produced by partial ovarian destruction. Accordingly, a group of partially castrated rodents was studied, with illuminating results.⁹ Some of these showed no alteration in either the estrous cycle or the microscopic appearance of the endometrium. Others showed prolonged stages of estrus with endometrial changes typical of glandular cystic hyperplasia. In still others there were few or no estrous cycles and an endometrium that was atrophic.

The next step was to investigate the effect of hypophyseal deficiency on ovarian function and endometrial response. A group of animals was partially hypophysectomized and showed the same responses that were observed in the partially castrated group.¹⁰ From these experiments one is forced to conclude that glandular cystic hyperplasia of the endometrium is not a disease but a clinical-pathologic symptom complex referable to at least two glandular disturbances and is only one of a number of such symptom complexes which result from them. Clinical studies have greatly extended this concept. In studying the endometrium of patients with menorrhagia and metrorrhagia by the serial biopsy technique¹¹ one finds many instances of bleeding originating in an endometrium showing clear-cut evidence of the action of estrogen and progesterone. At some subsequent period the same patient's endometrium may show a clear-cut endometrial hyperplasia. Likewise, cases of endometrial hyperplasia are seen which at some subsequent time show an endometrial atrophy.

In attempting to correlate the type of bleeding with the type of endometrium, one finds that no absolute relationship exists. There is, however, a tendency for the minor disorders to occur in cases showing a more or less normal endometrium, indicating a first degree ovarian failure. The severe bleedings usually occur from an endometrium characteristic of glandular cystic hyperplasia, indicating a second degree ovarian failure. Bleeding as well as amenorrhea is found in cases presenting an atrophic endometrium, indicating a third degree ovarian failure.¹⁰

Whatever the degree of ovarian failure, a careful examination of the patient will usually reveal evidence of some endocrine disturbance. The most common offenders are the pituitary, the thyroid and the ovary. Associated with the endocrine lesion one often finds such other conditions as anemia, focal infections, nutritional disturbances and nervous conditions.¹¹

Functional menorrhagia and metrorrhagia, therefore, are symptoms of an ovarian disturbance, either primary or secondary to diseases of the pituitary or thyroid, or secondary to some constitutional disease affecting one or more components of the endocrine system. The microscopic appearance of the endometrium is the indicator of the severity of the disturbance in ovarian function.

In any discussion of the use of endocrine products in the treatment of menorrhagia and metrorrhagia, one is faced with a difficult task, since these symptoms occur in a variety of disorders. It is beyond the scope of a single paper to discuss all possible applications in the treatment of disease. Therefore only the general principles governing their use are outlined.

The first and most important principle in the treatment of menorrhagia and metrorrhagia with endocrine products is that an accurate diagnosis is essential.¹² The underlying endocrine condition, as well as the general constitutional state of the patient, is determined.¹³ The degree of ovarian deficiency can be estimated from a study of the endometrium.

The second principle is the treatment of the existing endocrine lesions with specific measures. The most satisfactory results are obtained in hypothyroidism. A standard thyroid preparation is selected and administered in all such cases, thereby eliminating difficulties arising from variations in the strength of various extracts. In our experience it has been best to start with from one-half to three-fourths grain (0.03 to 0.05 Gm) of U. S. P. desiccated thyroid daily. After a period of two weeks, the dose is adjusted according to the patient's response. The adjusted dose is given for two weeks and the procedure repeated. The basal metabolism is determined at the end of six weeks and the dose of thyroid is increased until the metabolism is at or near normal, or until undesirable symptoms occur. If such symptoms do occur, the dose is reduced to the level at which the greatest effect can be obtained with the least undesirable reaction.

Any of the accepted gonadotropic products of pregnancy urine or of the placenta¹⁴ are useful in the treatment of abnormal uterine bleeding resulting from hypothyroidism. Their effect, however, is transient,

since the underlying hypothyroidism is not permanently influenced by their use. In primary ovarian disease the preparations are extremely valuable, since direct stimulation of the ovary is produced.¹⁵ While the patient is bleeding, from 100 to 500 rat units of the gonadotropic substance may be administered daily until the bleeding ceases. This should be followed by weekly injections of from 200 to 500 rat units. If it is impossible for the patient to be seen at frequent intervals, single massive doses are often effective.

Progesterone therapy for the direct replacement of ovarian insufficiency due to absent or abnormal corpus luteum would seem to have much to offer. Several recent articles reporting successful treatment have appeared.¹⁶ Effective therapy with a few injections of from $\frac{1}{25}$ to $\frac{1}{5}$ international unit (0.04 to 0.2 mg) has been reported.^{16b} Until recently its use has not been extensive, owing to the expense and difficulty of securing potent extracts. What its ultimate place will be in the treatment of abnormal uterine bleeding remains to be seen. It is to be remembered, in consideration of this form of therapy, that menorrhagia is at times present when there is evidence of ample progesterone secretion and, on the other hand, is often present in the absence of progesterone secretion. Factors other than progesterone, therefore, exert a profound influence on uterine bleeding.

In pituitary disorders there is often, in addition to the direct lack of pituitary secretion, a failure of the thyroid and ovary. Pituitary preparations in the form of desiccated whole pituitary substance (60 grains, or 4 Gm, a day) or one of the injectable preparations containing the essential anterior pituitary principles (100 units daily) are used. These preparations are often not effective alone. In such instances small doses of desiccated thyroid, an estrogen or gonadotropic substance may be necessary as supplemental therapy.

The third principle in the treatment of menorrhagia and metrorrhagia with endocrine products is the eradication of factors contributory to the primary disorder. Foci of infection should be diligently sought and treated. The body weight should always be adjusted to the normal. Any anemia should be corrected. Snake venom is often effective as a stopgap,¹⁷ its hemostatic action allows the correction of anemia and gives an opportunity for other measures to take effect. The diet should be made adequate, especially in proteins and accessory substances, and rest and sleep should be emphasized. Neglect of this third principle is a frequent cause of poor results from good endocrine products.

The final principle in the treatment of menorrhagia and metrorrhagia with endocrine products is the realization that surgery and irradiation produce only a symptomatic cure.¹⁸ They still have a definite and important place in treatment. But it must be remembered that the underlying pathologic condition is still

present and usually demands further treatment. Neglect of this final principle has been almost universal, and every gynecologist has patients who are cured of their menstrual disorder but who still have their primary disease.

THE ENDOCRINES IN RELATION TO STERILITY AND ABORTION

JENNINGS C LITZENBERG, MD
MINNEAPOLIS

The endocrines govern the physiology of reproduction from beginning to end, spermatogenesis, oogenesis, maturation of the ovum, ovulation, fertilization, preparation of the endometrium for nidation, implantation of the fertilized ovum, placentation, maintenance of pregnancy, development of the fetus, birth and lactation—all are dependent on hormones initiated and controlled by the anterior hypophysis.

The definite suspicion that something in the blood accounted for the phenomena which occurred when the ovaries were removed and a return to normal followed transplantation of ovarian tissue—this was the real inception, even if not the first hint, of the endocrine idea. Then the search for the mysterious substance began, fruitless as to conclusions for many years but very rich in laying the foundations for our knowledge, limited though it is, of the physiology of reproduction.

One needs only to mention a few who placed stones in this foundation which made the recent great advancements possible, and to remind oneself how important pioneer work is. Fraenkel¹ and his corpus luteum experiments, Hitchmann and Adler² with their rediscovery of the cycles of the endometrium, Meyer³ and Schroeder,⁴ who helped to establish the concomitant cycles of ovary and endometrium, Stockard and Papanicolaou,⁵ whose discovery of the cyclic changes in the vagina of lower animals still more firmly established the synchronicity of the ovarian and endometrial cycles and the control of the latter by the former and greatly fostered animal and human endocrine research.

Knowledge began to crystallize when Robert Frank⁶ in 1922 and Allen and Doisy⁷ in 1923 independently demonstrated the hormone activity of the follicle fluid. The pursuit of the elusive factor seemed accomplished, but there was yet another to come, which Novak⁸ and others had predicted, because the microscopic appearance of the endometrium indicated that there should be some principle, probably from the corpus luteum, which would complete the ripening of the endometrium into the progestational phase, to them the endometrial picture seemed incomplete. Their prediction came true when Corner and Allen⁹ in 1928 extracted from the corpus luteum of rabbits a substance which they called "progestin." "This had exactly the effects presupposed

for it."⁸ Now four hormones were known, for Smith and Engle¹⁰ in the United States and Aschheim and Zondek¹¹ in Germany in 1927 had completed the chain of glands immediately involved in the female physiology of reproduction and demonstrated the dominant rôle of the anterior hypophysis in the reproductive system. This predominance of the gonadotropic principle on the endometrium, through the agency of the estrogenic substances of the ovary, is too familiar to require repetition. However, there are two other active principles found in the urine similar in their action to the gonadotropic principles of the hypophysis, the gonadotropic substances of pregnancy urine or of the placenta. These six hormones are the known factors concerned in the physiology of reproduction. However, their very complex mechanism still eludes complete solution, just enough to leave their therapeutic use very unsatisfactory.

Since all these endocrine forces are recognized, any failure, derangement or deficiency in this succession of endocrine events may result in sterility and abortion. Other glands have some influence on fertility, for example, the adrenals, the hypothalamus, the pancreas and particularly the thyroid.

I shall not have time to discuss their as yet rather obscure effects, with the exception of the thyroid, which is a very definite factor in the physiology of reproduction. Therefore, in the diagnosis of the causes of infertility, sterility and abortion, one must investigate the three glands most frequently involved—the pituitary, the ovaries and the thyroid—and the offending gland must be determined, which can usually be accomplished with reasonable accuracy by clinical data—the knowledge of the stigmas of the various endocrine types, the details of which have no place here but may be found in treatises on endocrinology, such as Frank's "The Female Hormone,"¹² in which will also be found the technique of laboratory tests for the active principles in the blood and urine.

Much has been learned about the physiology of reproduction, but it must be confessed that only the framework has been erected. Much material must yet be accumulated and put in place before the edifice can be completed. Therefore knowledge of the endocrine factors involved in sterility and abortion are truly scanty, as Novak⁸ has put it: "As a matter of fact, there are only a few aspects of the problem sufficiently crystallized to justify discussion." It is interesting, if not profitable, to consider a few of the functional disturbances usually accompanied by sterility.

FUNCTIONAL AMENORRHEA

When a woman has never menstruated, she usually has never ovulated and cannot conceive. There is no known way, as yet, of producing ovulation in women, such as can be done by injecting pregnancy urine in some lower animals. Amenorrhea, attended by sterility, is frequent in pituitary endocrinopathies. When uncertain of the diagnosis by clinical observation, hormone blood and sugar tolerance estimations, and x-ray examination of the sella turcica will often complete the necessary evidence.

When amenorrhea is incomplete or when there is oligomenorrhea, the ovary has demonstrated its ability

to ovulate, although inadequately. This type is quite apt to respond to treatment.

That the ovaries are sometimes primarily deficient is shown by a large amount of pituitary hormones, by laboratory tests, and by the absence of estrogen, a sure sign of ovarian hypofunction. Treatment by estrogenic substances is useless, for no endocrine gland is stimulated by its own product. Furthermore, the effect may be injurious. The gonads are not self-regulating, the seat of such control is in the hypophysis.¹³ Hypophysis products and the gonadotropic product of pregnancy urine or of the placenta have, in our hands, been very disappointing. We have had better results with thyroid, even when the basal metabolism is not markedly low.

Functional bleeding is usually accompanied by sterility because both the hemorrhage and the sterility are due to functional abnormality of the ovaries, which produces an excessive amount of estrone, causing a hyperplasia of the follicular phase of the endometrium and, on account of the failure of ovulation, no progesterational endometrium is formed. This usual explanation of the condition may have to be altered.

Burch, McClellan and Johnson,¹⁴ by animal experimentation and cannula curet biopsies of human endometrium, found three degrees of endometrial abnormality.

First, functional bleeding, usually moderate, with luteal endometrium.

Second, menorrhagia, with aluteal endometrium and cystic glandular hyperplasia.

Third, aluteal atrophic endometrium, with a tendency toward amenorrhea.

They concluded that the disorders of menstrual interval and flow are the result of ovarian underfunction, the severity of which is indicated by the state of the endometrium, and that the underfunction may be primarily ovarian or secondary to lesions in other endocrine glands.

Hamblen,¹⁵ reporting 358 consecutive endometrial biopsies from women with functional bleeding, found four different endometrial patterns, of which the vast majority were of the estrogenic stimulating type, but only 45 per cent showed the classic pattern of endometrial hyperplasia.

Evidently cannula curet biopsies are upsetting some former ideas, as careful research has a disconcerting way of doing.

The treatment must inevitably be adjusted to the type of endometrium found but, since cystic glandular hyperplasia is the predominant type, perhaps the use of progesterone will still remain the rational treatment. Gonadotropic substances in the past have given variable success, sometimes spectacular and the very next time an utter failure. I imagine that cases presenting a low basal metabolic rate will continue to give reasonable results.

ANOVLATORY MENSTRUATION

Menstruation without ovulation was called to the attention of the profession by Corner¹⁶ and Hartman¹⁷ by their discovery that at certain times monkeys menstruated without ovulation. Novak and many others have demonstrated by means of the cannula curet that the endometrium of some women show no progester-

tional changes, therefore these women have not ovulated and of course cannot conceive.

There is no treatment at present.

Habitual abortion and sterility are closely allied because the same endocrine factors are involved. The influences vary from normal, through low fertility, to sterility. When a woman of low fertility conceives, the endocrine factors that preserve the pregnancy—for example, progesterone from the corpus luteum of pregnancy—may be insufficient and she aborts, therefore treatment with progesterone is logical.

Bishop, Cook and Hampson¹⁸ found progesterone valuable in habitual and threatened abortion.

Krohn, Falls and Lackner¹⁹ reported nineteen cases treated with progesterone, of which 74 per cent were successful.

DEFECTIVE GERM PLASM

The confused state of the etiology of abortion assumed a more scientific aspect when His, and later Mall²⁰ and Streeter,²¹ found that embryologic defects—defective germ plasm—were frequent causes of fetal death and abortion. Mall thought it was caused by poor environment, i. e., a faulty endometrium and resultant improper nourishment. Robinson, on the other hand, thought the difficulty was inherent in the ovum itself because some ova were faulty and others perfect in litters of ferrets. Either theory is compatible with endocrine deficiencies.

ENDOCRINE TREATMENT OF STERILITY

With our present knowledge of the physiology of reproduction and the known dominance of the anterior hypophysis through the gonadotropic hormones, it would seem logical to employ preparations of them in most cases of sterility. One cannot be too critical of their use experimentally, but their exploitation is reprehensible and their indiscriminate use unwise.

Because of my own unsatisfactory results with the hypophysis extracts and the gonadotropic products I have made a searching review of the clinical reports in the literature, but I remain unimpressed, though hopeful.

Isolated reports of success are without value. Scientific statistical formulas cannot be applied to small series, and most reporters seem not to take into consideration the number of cases which spontaneously return to normal, which Frank emphasizes thus: "I have so often seen improvement or cures in amenorrhea and sterility, without any therapy, that I am fully convinced that therapeutic results, so frequently found in the literature, are accidental or coincidental."

Much, perhaps most, of the trouble is due to the gaps in our knowledge, which in due time will be filled, much is due to misinformation, much to credulity and much to overenthusiasm and uncritical use of endocrine products.

I am quite as critical of my own figures given here as I am of the figures of others. I realize that the cases reported are relatively small, too small to apply statistical formulas. They are given only as evidence and not as proof.

THE THYROID AND STERILITY

Since 1922 I have studied the relation of the basal metabolic rate to sterility, abortions and menstrual dis-

turbances In our first small series of sixty-nine²³ consecutive sterile women, in whom no other evidence of myxedema was present, 50 per cent had a low basal rate, adding those who had conceived but aborted, the figure was 56 per cent Carefully supervised thyroid medication resulted in 33.3 per cent conception, 14 per cent of whom aborted One woman conceived three times under thyroid medication, bringing the percentage of conceptions to 40 In another group of 114 women, 45 per cent of the married women were sterile and 40 per cent of the entire group had functional disturbances of menstruation In a second series²⁴ of 137 women, approximately the same figures were obtained, but in addition we found that 63 per cent had abnormal menses (our patients all came from a goiter area)

Our third series (including the previous reports) consists of 255 married women, 49.7 per cent of whom were sterile Of 332 women, married and unmarried, 33.5 per cent had functional disturbances of menstruation During the fifteen years of our experience to date (including cases not previously reported) there was a consistent rate of conceptions of 30 per cent in women with low basal rates

Haines and Mussey of the Mayo Clinic²⁵ confirmed our thyroid treatment of functional menstrual disturbances, saying "Because of a desire to determine the effectiveness of thyroid medication alone, in the treatment of certain menstrual disturbances, no patient received any other treatment All were definitely improved, amenorrhea, 72 per cent, oligomenorrhea, 55 per cent, menorrhagia, 73 per cent, and general health, 75 per cent"

Also in this connection Haskins²⁶ says "Most gynecologists agree that thus far of all the gland products, thyroid has proved to be the most useful for a variety of endocrine disturbances, including amenorrhea, oligomenorrhea, menorrhagia, sterility and abortion"

Marine, long ago (1917) when there was scarcely any usable knowledge of the endocrines, declared "The relation of the thyroid to the sex organs in the female is the most frequent and classical illustration of the interrelation of the function of glands with internal secretions"

Frank adds testimony by saying "The sole endocrine preparation that has proved itself of real value has been thyroid extract, which is of use in patients with lowered basal metabolism"

Novak⁶ declared that thyroid medication in sterility and abortion are more often efficacious than any other form of organotherapy

Desiccated thyroid was the first, and is still one of the few successful, substitutional hormone preparations Perhaps when one gives desiccated thyroid one is doing to the ovaries what the pituitary has failed to do through stimulation of the thyroid gland by means of the thyrotropic hormone

I quote the concluding paragraph of an editorial in THE JOURNAL²⁷

These reflections [criticisms of the misuse of sex gland hormones] are not intended to inhibit chemical and biologic studies in accredited laboratories Neither do they apply

to the carefully controlled clinical application of accepted knowledge by competent observers, this is necessary Rather are they intended (1) to emphasize that there is a great discrepancy between laboratory knowledge of the hormones and their clinical application, (2) to suggest that for the present only those clinicians with facilities for critical study be encouraged to administer the newer endocrine preparations to patients and that these clinicians be urged to publish their negative as well as their positive results, and (3) to suggest that a large group of physicians not represented in either of the groups mentioned cease their indiscriminating injection of unknown substances into unsuspecting patients

Physicians are perhaps cynical because of our limited knowledge of the endocrines and the complexity that faces it, but the tendency is to optimism when it contemplates the accomplishments of the recent past with their great promise for the future

ELEANOR L. ADLER, M.D.
NEW YORK

In 1933 one of us (Lewis¹) showed that by administering estrogenic substance it was possible to change the thin vaginal mucosa of the child to that resembling the thick epidermis-like structure of the adult This change is a temporary one and subsides when treatment is withdrawn, with a reversion to the normal vaginal mucosa characteristic of childhood Together with the report of this observation were recorded eight cases of gonorrheal vaginitis in children, treated with estrogenic substance Most of these were treated with hypodermic injections of aqueous solutions of the principle In some, estrogen suppositories were used as adjuvants All were improved and some cured

Later we² reported that the building up of the vaginal mucosa in this way produced a strongly acid vaginal secretion like that of the adult menstruating woman Before puberty and after the cessation of ovarian activity the vaginal mucosa is a delicate thin structure with a so-called secretion, which is neutral or faintly acid During these years it is an easy prey to invasion by pathogenic bacteria, gonococci in particular Long ago Doderlein taught the important role that the acid vaginal secretion of the adult plays as a protection from infection Gonococci as well as many other organisms perish in vitro if the p_H of the medium on which they find themselves is lower than 6 In patients treated with estrogenic substance the vaginal acidity often drops to 5 or below When the hydrogen ion concentration is kept below 6 we usually fail to recover gonococci from vaginal smears or cultures In

E. R. Squibb & Sons gave us the large amounts of amniotin used in the treatment of the cases that we have reported

Drs. Benson, TeLinde and Mazer have permitted us to include in this paper some of their work that has not been published

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1937

A grant from the Milbank Fund made possible the study carried on under the Department of Pediatrics of New York University Medical School in the Children's Medical Service of Bellevue Hospital Also facilities were extended to us by the Yale School of Medicine

short, we believe that the production of a marked vaginal acidity is an important adjunct in effecting cures in these cases

By treating a small series of children with gonorrheal vaginitis with quite large amounts of ethylene glycol amniotin hypodermically, we cured the disease in an average of 24.2 days. These results were confirmed by some clinics, although others did not meet with the same therapeutic success. Mazer and Israel⁵ reported good curative results using large amounts of estrogenic substance subcutaneously, but they noted also such by-effects as enlargements of the breast and rarely slight menstrual discharges.

Happily TeLinde and Brawner⁴ used vaginal suppositories of amniotin and at once obtained brilliant results, obtaining cure in seventeen successive cases of gonorrheal vaginitis. This method is very advantageous because it is not disturbing to the patient, can easily be administered by an intelligent mother and requires such small amounts of the substance that no undesirable effects are known to have occurred.

According to our own experience, treatment solely with vaginal suppositories as described by TeLinde and Brawner⁴ has proved vastly more simple and effective than the use of hypodermic or oral preparations. We shall here summarize our results in eighty-two cases of gonorrheal vaginitis in children treated only with amniotin suppositories in the Children's Medical Service of Bellevue Hospital, New York. The recent results of other clinics, furnished us in personal communications, are also included.

To be specific, this form of treatment consists in the insertion of a gelatin capsule containing 75 rat units of amniotin, or one half of an amniotin suppository, into the vagina each night at bedtime. (One half of a suppository contains 1,000 international units of estrogenic substance.) No douches are used, but at first the external genitalia may require cleansing if the discharge is profuse.

At the Bellevue Hospital we found that in 107 courses of such treatments the vaginal smears became negative (absence of pus and gonococci) on an average in twenty-four days. A few patients required many weeks before negative smears were obtained, on the other hand, some cleared up in a very few days. Satisfactory results require faithful daily treatment. Some of our patients required unduly long treatments because this fact was overlooked.

Of a total of eighty-two patients with gonorrheal vaginitis adequately treated with amniotin suppositories alone in the Children's Medical Service at Bellevue to April 15, 1937, two were not cured. The remaining eighty are apparently well. Twenty-nine have been cured for over one year, twenty-one for over six months and the other thirty have been apparently well (negative smears and the like) for from one to six months. One of the two uncured cases was puzzling because there was no physiologic response even after the administration of large amounts of the substance.

Together with others using this method of treatment we found that reinfections and recurrences were a serious problem. Twenty-five of our eighty patients returned from their homes again with vaginitis after having been apparently cured. We believe that most of these cases were reinfections. At least we know that in the homes of twelve of these children there

were other persons with gonorrhea. It seems probable that these patients reacquired infections from their original sources. One case recurred while the patient was in the hospital, but we have reason to believe that this was also a reinfection. These patients, when they returned, were cured by being treated as before with suppositories. It is of interest that patients treated a second time usually get well more quickly than do patients having their initial treatments. We believe that all patients should be under observation for at least one year after they are apparently cured. They should be kept from intimate contact with other girls for at least the first six months of this time. It seems unnecessary to add that, if the treatment with suppositories is unsuccessful, a careful investigation of the cervix, urethra and rectum must be made. We have found but few instances of persistent endocervical infection.

Mazer and Israel⁵ treated sixty cases of gonorrheal vaginitis with hypodermic injections of from 1,000 to 1,500 rat units of estradiol benzoate every other day for eight weeks. These cases showed the physiologic by-effects previously mentioned. In the sixty cases there were five recurrences. Mazer⁵ writes that he has now treated thirty-five children with vaginal suppositories containing estrogenic substance. Only sixteen of these have been treated long enough to permit a follow-up of from three to six months, but all were apparently cured and in only one case was there a recurrence. Mazer believes that all patients should be treated for at least eight weeks to insure against recurrence, and we agree with this policy.

Benson and Steer⁶ have reported the hypodermic treatment of eighty patients with different preparations of estrogenic substance. Sixty-six were apparently "cured" but in nearly all the condition recurred. In a later group of ninety-two cases Benson⁷ used amniotin capsules intravaginally for an average of twenty one days. Negative smears and apparent cures were obtained, but after the patients returned to their homes about one half were reinfected or the condition recurred. He observes⁶ that "an analysis of these cases would seem to indicate in general that those showing recurrence were the ones returned to unclean homes, while those that remained cured went back to clean homes or child caring institutions where there was no contact with infected cases." Benson believes also that apparent recurrences after discharge from the hospital are usually reinfections. Possibly longer treatment of these cases might have reduced the number of recurrences.

Richard W. TeLinde⁵ writes that in his clinic in Baltimore 140 cases of gonorrheal vaginitis have been successfully treated with amniotin suppositories. The first 100 have been reviewed. In this number the condition has recurred only twice or the patient has been reinfected, one six and one seven months after treatment was stopped.

The cost of the suppositories of estrogenic substance used in the average case is not excessive for the private patient (amounting as a rule to eight or ten dollars). Since only relatively small amounts of estrogenic substance are given by suppositories, it is our opinion that the treatment is not dangerous. No ill effects have been seen. However, we advise against the administration of large doses of estrogenic substance over a long period of

time as possibly injurious, although there is no conclusive evidence of harmful results following such treatments

Karnaky⁸ has advocated using acidulated sugar in the vagina combined with occasional douches of dilute acetic acid. Little⁹ states that he has treated thirty-nine cases of gonorrheal vaginitis in this way, with the number of days required to effect a cure averaging 98.5. At present the number of our own cases in which this method of treatment was used is too limited to report. Sugar tablets must be inserted into the vagina two or three times a day. In our experience the vaginal secretions are not acid if measured some hours after the sugar tablets are dissolved. We have had but little experience with sulfanilamide and wait with interest to learn what value it may have in the treatment of gonorrheal vaginitis.^{10a}

Until recently the treatment of senile or postmenopausal vaginitis has been most unsatisfactory. After cessation of the secretion of estrogen following the menopause or castration, the vaginal mucosa reverts to the thin, ill developed structure of childhood. The secretions are no longer acid and the mucosa becomes once again easily infected. When infected, such patients complain of burning, itching or pain in the vagina, and coitus may be painful or impossible. The appearance of the vaginal walls as described by Davis¹⁰ and others is characteristic. In 1935 Davis reported remarkable success in treating these cases with amniotin subcutaneously. In the majority of his cases he administered 100 rat units of amniotin hypodermically three times a week. The average duration of the treatments was six weeks. Vaginal suppositories alone did not give satisfactory results. Usually complete symptomatic relief was afforded in about ten days. Biopsies taken at intervals during treatment showed the development of the vaginal mucosa in appearance exactly similar to that of a woman during the years of menstrual life. The vaginal secretions also became acid. Davis states that ordinarily the treatment of such patients should be continued for from six to eight weeks, for if any infection or inflammation remains the symptoms will return soon after it is stopped. In any event, when treatment is stopped the vaginal mucosa reverts to that of the childhood type, and if the factors that were responsible for the original infection are again encountered reinfection will follow.

Others have confirmed Davis's observations. Jacoby and Rabbiner,¹¹ for instance, report like results in twenty-five cases.

In our own experience, results have been good when the condition treated was a typical senile vaginitis. Vulvar leukoplakia has not been benefited. We have had two cases, one after removal of the ovaries and one following intra-uterine irradiation, in which the shrunken vagina became so dry and sensitive that intercourse was impossible. In both instances treatment with amniotin was effective in relieving the situation. It is probable that, as well as building up the vaginal mucosa secretion from the cervix and Bartholin's glands was restored.

Five years ago the treatment of vaginitis in children and in women after the menopause was anything but satisfactory. These newer methods of today are yielding gratifying results.

CONCLUSION

We have had better results with the use of estrogen suppositories than with hypodermic treatments with estrogen preparations.

THE ENDOCRINE TREATMENT OF MENOPAUSAL PHENOMENA

J P PRATT, MD

AND

W L THOMAS, MD

DETROIT

The menopause is an event which has attracted wide attention among the public as well as among members of the medical profession. A variety of symptoms have been attributed to the critical change in a woman's life. A sharp distinction between the physiologic and the pathologic manifestations during this epoch of life has rarely been made. A causal relation between the symptoms exhibited and the physical changes in the body have been frequently assumed but seldom established. Numerous procedures and materials have been advocated for relief or cure, but proof of their specific efficiency is usually lacking. In recent years, special attention has been directed to endocrine preparations as therapeutic agents for relief of menopausal symptoms. In the present study of endocrine therapy, control observations have been used.

MATERIALS

The materials selected for study of the menopause may be divided into capsules and compressed tablets for oral administration, and sterile ampules of oil for hypodermic injection. The capsules, which were identical in appearance, contained theelol, phenobarbital or lactose. The compressed tablets, which were identical in appearance, contained either emmenin or lactose. The ampules contained either oil alone or theelin in oil. For identification, the preparations were given a code number, which was changed frequently to keep the one prescribing them ignorant of the nature of his prescription. One of us changed the code number from time to time without informing the one who administered the preparations. Before the preparation of the unknowns was completed, eleven patients were treated with phenobarbital and six with bromides. With these seventeen exceptions, the agent prescribed was unknown until final observation was recorded.

METHOD

Two hundred consecutive menopausal cases were studied over a period of several months. Only 100 of the subjects returned often enough to justify tabulation. A complete clinical record was written, including history, physical examination and routine laboratory tests of blood and urine. By means of a special form, the presence or absence of most of the symptoms

^{10a} Since the writing of this paper treatment with sulfanilamide has been completed in a series of seventeen cases of gonorrheal vaginitis in children. In nine of the cases the results were dramatic with clearing of discharge and negative smears developing in twenty-four and forty-eight hours. Inadequate dosage probably accounts for the failure of three cases to respond; therefore treatment with sulfanilamide has been successful in nine of fourteen adequately treated cases.

commonly attributed to the menopause was tabulated. Environmental and emotional states varied so greatly that they did not lend themselves readily to tabulation, therefore, individual records were made. The symptoms investigated were taken from the current medical literature, which suggests that these symptoms belong to the menopause. Our observations failed to confirm this relationship in many instances, e g, arthritis and hypertension. The list included changes in the menstrual cycle, hot flushes, headache, languor, vertigo, palpitation, insomnia, digestive disturbances, paresthesia, neuralgia, arthritis, weight change, trend toward masculinity, impairment of memory, emotional instability, depression, melancholia, extreme irritability, agitation, apprehension, delirium and suicidal tendency. After voluntary statements were accepted, leading questions were asked, to complete the record. Physical examination included observation on weight change, fat distribution, genital involution, blood pressure change, pulse rate, evidence of arthritis and signs of masculinity. Laboratory tests included bio-assay of the urine in only a few instances and are therefore not reported. Geist¹ has recently called attention to the lack of correlation between excretion of hormones and menopausal symptoms.

Results

Drugs	No of Cases	Complete Relief	Improved	Doubtful	No Relief	Per Cent Completely or Partially Relieved
Unknown

Concurrent diseases and conditions which were not menopausal were treated as indicated.

All patients were sufficiently intelligent and informed to be aware of the popularly accepted relationship between failing ovarian function and menopausal symptoms. When treatment was prescribed, the patient inferred that she was receiving some ovarian preparation. Since the nature of the preparation was unknown at the time it was prescribed, the observer was unable to correct the patient's assumption.

The dosage was varied according to the severity of symptoms and the response obtained. One or two capsules or tablets were given from one to three times a day. Injections were given daily for a period of from five to ten days. After varying intervals, the injections were repeated as indicated by the results obtained. The total amount of theelol given to a single patient in the course of treatment varied from 2 to 5 mg. The total amount of theelin varied from 12,000 to 96,000 international units (12 to 96 mg). No untoward effect was noted in any instance.

Patients who did not return regularly for observation were not included in the final tabulation of results. This excluded many who were entirely relieved by the first course of treatment and therefore failed to return. Those who had few or no symptoms besides cessation of menstruation were also excluded.

Many different personality types were encountered but the patients were not classified according to this criterion. The psychotic patients were observed by a psychiatrist. These patients were retained in the hospital not less than three months. Not one of this group was improved.

The use of a placebo is by no means new. Practically every physician of experience has used it at one time or another. It has rarely been used, however, as a check to determine the value of hormone therapy in the human being. A similar experience was recently reported by Aschner and Buch Casamor² in treating gonadal dysfunction in the male. Satisfactory results were obtained in males when no hormones were used if the patient believed that he was receiving gonadotropic stimulating therapy.

COMMENT

The term menopause has been used with the generally accepted broad interpretation. Etymologically it means merely a physiologic cessation of menstruation. The climacteric, or critical age, signifies a period of life characterized by a complexity of phenomena, the most conspicuous of which is the cessation of menstruation. No term accurately distinguishes between physiologic and pathologic processes. The menopause, though loosely used, is popular among the public as well as the medical profession to express the concept of the period of transition in a woman's life from the reproductive period to senility.

The average age of women in this series at the time of observation was 45.6 years. The average age at the onset of the symptoms was 43.5 years. Eleven of the patients had an artificial menopause. The average time that elapsed between the operation and the onset of the first symptoms of the artificial menopause was ten weeks. In general, the symptoms of the artificial menopause were more severe than were those of the natural menopause.

Hot flushes are such a constant symptom of the menopause that no patients are included in this series who did not have this symptom. The frequency and duration of the flushes were recorded but showed rather wide variation. In general, they are a good indicator of the severity of the condition. Some of the patients are more impressed by the sweats than by the flushes. The degree of relief from the flushes and the sweats is the best single indicator of the amount of improvement obtained. For the sake of accuracy in estimating results it is unfortunate that the best criterion is subjective.

Languor was the second most frequent symptom noted in this series. There is no satisfactory measure of the degree of languor besides the impression of the individual experiencing it. Other contributing factors than the menopause were frequently responsible for languor. Among these may be mentioned anemia, hypothyroidism and emotional disturbance.

Different observers agree that approximately 85 per cent of women pass through the menopause without interrupting their daily routine. The 100 cases presented here belong to the remaining 15 per cent, since only those women were included who came for treatment of symptoms of the menopause.

The menopause is a conspicuous event in the life of most women. Environmental changes are frequent and often profoundly influence the life of the individual.

¹ Geist, S. H. and Mintz, Maurice. Pituitary Radiation for the Relief of Menopausal Symptoms. *Am J Obst & Gynec* 33: 643 (April) 1935.

² Aschner, Berta and Buch Casamor, A. Zur Klinik des Senilnuchondismus und Spätkastrations. Zugleich ein Beitrag zur Therapie. *Klin Wchnschr* 14: 86 (Jan 19) 1935.

These changes are too diverse to permit detailed discussion here. The tabulation of results gives no indication of the importance of this factor. In every instance, however, the environment was given careful consideration.

It is realized that 100 cases is a small number from which to draw conclusions. They are sufficient, however, to establish a trend. The method was chosen because it was one means of controlling observations. Medical literature contains an abundance of impressions without controls.

It is interesting to note in the tabulation of results that, regardless of the form of therapy, the majority of patients were relieved or improved. Furthermore, there is only a slight difference indicated for the different agents used.

The question arises whether those who failed to obtain relief would have been benefited by larger doses of theelin or longer periods of treatment. One of the patients in whom treatment failed received more theelin than any other patient. She was subjected to one environmental shock after another. During a three months vacation, however, she was living under ideal circumstances and remained symptom free, although she received no therapy at all. When she returned to the city, the unfavorable environment was again encountered and all her symptoms returned. She resented strongly the necessity of an artificial menopause. She was a highly sensitive woman who responded excessively to ordinary environmental stimuli.

The other failures are still under observation. They are being studied intensively to see whether they represent a group in which the symptoms of ovarian failure predominate. Other factors are being eliminated in an attempt to isolate ovarian deficiency as a primary cause.

One of the patients presenting the menopausal syndrome was seen by a psychiatrist ten years before. She presented identical symptoms on the two occasions. At the time of the first visit she was menstruating regularly and showed no signs of genital involution. The diagnosis at that time was anxiety neurosis. When seen ten years later for the same symptoms, she had ceased to menstruate and showed genital involution. The diagnosis was menopausal syndrome. In both instances she obtained striking relief from sedation. The frequent resemblance of menopausal symptoms to the symptoms of anxiety neurosis cannot be overlooked.

Life is a continuous process. During the reproductive period there is a gradual waning of ovarian function. The transition from the reproductive period to senility is physiologic and gradual. It is not a crisis. The transformation involves the body as a whole, though the change in the ovaries and the organs under their direct control is most conspicuous. In the majority of instances, it is illogical to assume that substitution for failing ovarian secretion will alter the whole body and arrest the natural aging process.

The symptoms occurring at the time of the menopause are complex. Many diseases and pathologic states may be concurrent with the menopause. Is the menopause an entity? Inclusive consideration of all menopausal symptoms really involves a large part of the field of medicine.

CONCLUSIONS

1 The symptoms attributed to the menopause are so diverse that it seems unreasonable to consider that all of them are due to ovarian failure alone.

2 The menopause is a term used loosely to indicate the physiologic transition in the life of a woman from the reproductive period to senility.

3 Pathologic conditions occurring at the time of the menopause should be distinguished from physiologic states.

4 Estimation of the merits of any form of therapy for the menopause should be based on the relief of pathologic symptoms and not on changes in physiologic states.

5 Equally good results may be obtained by many agents used empirically.

6 Substitution therapy should be reserved for those cases in which the pathologic symptoms can be demonstrated to be due to ovarian failure.

7 The method used in this study offers one means of selecting cases probably due to ovarian failure.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs FRANK, GOLDBERGER, SALMON AND
FELSHIN, DRs BURCH, MC CLELLAN, SIMPSON,
JOHNSON AND ELLISON, DR LITZENBERG,
DRs LEVINS AND ADLER AND DRs
PRATT AND THOMAS

DR EMIL NOVAK, Baltimore. The paper by Dr Frank and his co-workers emphasized again that physicians are still floundering in the treatment of amenorrhea. The groups which they described on the basis of hormonal studies are not unlike those which can be demonstrated by serial endometrial biopsy. For example, in amenorrhea one may find a persistently scanty and atrophic endometrium or one which exhibits an essential normal cycle (except for the bleeding phase), or one may find a typical hyperplasia, this last corresponding to the polyhormonic hyperplasia described by Zondek. In the same way, endometrial studies show that excessive menstruation can occur from almost any type of endometrium. Most characteristically one finds some degree of hyperplasia, but often the endometrium is of a normal interval type or even quite atrophic. Even a secretory endometrium may be seen in certain types of functional bleeding. The papers we have heard today illustrate the usual inadequacy of blood and urine hormone studies in pointing the way toward successful treatment. Valuable as such studies are from a scientific standpoint, they are not readily practicable in the vast majority of cases, and I believe that in the present state of our knowledge endometrial studies will often furnish just as valuable information of ovarian function, and far more simply. I do not like the use of the term ovarian deficiency by Dr Burch and his co-workers in the explanation of functional bleeding. Ovarian substance, or hypophysis-ovarian imbalance, would seem to be the underlying factor in these quantitative menstrual disorders, whether in the direction of excess or deficiency. It should not be forgotten that typical hyperplasia per se has nothing to do with uterine bleeding. It represents simply a maximum effect on the particular endometrium of a growth hormone, estrogen, which exerts a special growth effect on genital mucous membrane. But bleeding does not necessarily parallel this growth effect, for the bleeding "spill" may occur at almost any level. All physicians have seen cases of marked hyperplasia associated with long continued amenorrhea. Dr Burch states that the degree of endometrial change corresponds to the severity of the bleeding, an observation which does not agree with mine. The thyroid type of either menstrual deficiency or excess offers the best results in treatment, but unfortunately it constitutes only a small proportion of all cases. I agree with Drs Pratt and Thomas, and thus could be stated almost a priori, that many symptoms are unjustifiably attributed to the menopause. They include in the symptoms studied in this group of cases such indefinite manifestations as languor, digestive symptoms, impairment of memory and many others of this very subjective group. Dr Frank, formerly almost an organotherapeutic nihilist, has shown how adequate estrogenic therapy in menopausal cases brings

about disappearance of gonadotropic substances in the urine, with corresponding improvement in the patient's symptoms

DR. ELMER L. SEVRINGHAUS, Madison, Wis. The discussion of Drs. Lewis and Adler shows how a physiologic mechanism can be used for a pharmacologic purpose. They applied estrogen not as substitution therapy, which is the usual goal of hormone therapy, but to facilitate healing in an infection. There is excellent agreement among the different clinics trying this therapy, which is a real contribution to the cure of vaginitis. This concept of the pharmacologic use of a physiologic process explains many results with thyroid therapy. Nearly all these disturbances in the field of gynecology are hypofunctional. The one exception might be the menopause, in which with underfunction of the ovary, or absence of function after castration, there is excessive activity of the anterior pituitary in producing the gonadotropic material. The thyroid hormone tends to stimulate the rate of activity of all tissues. Consequently, stimulating results on the pituitary and the ovary may be expected from thyroid therapy. I think that is why results are seen from use of thyroid in amenorrhea and menorrhagia. Dr. Litzenberg's statement that his patients are uniformly hypothyroid needs comment. The normal basal metabolism of women is at least 5 per cent below zero, which means merely that our standards were set prematurely. Until a woman has a basal metabolism of -15, she must be considered within normal limits. The big problem before gynecology and endocrinology now is to determine how much deficiency exists in a given patient, and then to know how much material to give in a therapeutic program. Dr. Frank is studying these cases quantitatively. These studies are still to be reserved for the highly experimental clinics, because assay techniques are far from being uniformly reliable, and the significance of the urinary estrogenic output, as compared with the amount circulating in the blood and active within the body, is not known as yet. Obviously, the amount in the urine represents only a small fraction of that which is active, and until a considerable number of normal individuals are studied we cannot make even an empirical decision as to the significance of that urinary excretion. I am at a loss to know what Drs. Pratt and Thomas mean by contrasting the physiologic and pathologic disturbances of the menopause. All these vasomotor and psychic symptoms may occur in patients before the menopause, but the significant thing is that, after castration of a woman who has no other disturbances, these are the symptoms reported. They occur frequently in the spontaneous menopause. There is, conversely, the experience that all these symptoms can be abated and usually completely relieved by the use of an adequate dose of estrogenic materials. Drs. Pratt and Thomas did not tell how much of the estrogenic substance per day is employed in a case. The necessary dose varies tremendously. For the present at least it would be well to stay with the standardized preparations from manufacturers who have been making these materials long enough so that one knows the materials are what the labels say they are. Estrogen will accomplish results either orally or by injection. I would prefer to stay away from the parenteral use of a foreign oil which leads to foreign body reactions, using only the oral preparations.

DR. E. C. HAMBLEY, Durham, N. C. Drs. Lewis and Adler have proved conclusively the specific vaginal effects of estrogenic principles. Drs. Pratt and Thomas have described the generally appreciated psychotherapeutic associations of the treatment of so called menopausal symptoms. Larger doses and more prolonged administration of estrogenic principles in oily solution than Drs. Pratt and Thomas used are necessary to secure pituitary depression as judged by urinary hormone assays. Some of the failures reported by Drs. Pratt and Thomas might have responded to more prolonged therapy. The therapeutic employment of estrogen and progesterin in my experience has permitted the conservative management of many of the anovulatory types of functional menometrorrhagia. In addition to a local endometrial effect, there results beneficial depression of the pituitary permitting rest and restitution of the exhausted ovaries. Such treatment may be exhibited at the time episodes of bleeding occur or may be employed cyclically following an initial curettage. Doses similar to those employed for full endometrial proliferation in castrates are frequently necessary. Such therapy is too expensive at present to warrant

its general use. The employment of the so called gonadotropic principles in functional anovulatory phases, responsible in many instances for menometrorrhagia, amenorrhea and sterility is the hope of initiating physiologic exocrine and endocrine responses in such ovaries, has been widespread and uncritical. Such principles, even when exhibited in doses much larger than those in general use, possess no claims for specificity. Among fifty-one patients with ovaries presumed to be in anovulatory phases, I have observed no evidence of any specific effect from such therapy as judged by the finding of corpora lutea at laparotomy, or by finding a progestational reaction in the endometrium. Daily doses as large as 8,000 rat units, and total doses as large as 24,250 rat units, given over a period of eight days, have been employed. In a recent series of thirty-seven patients with functional anovulatory menometrorrhagia who were treated during episodes of active and excessive uterine hemorrhage, only six showed any diminution in the amount of bleeding during such therapy. I agree with Dr. Litzenberg that thyroid extract is our main standby in endocrine therapy.

DR. FRED H. FALLS, Chicago. My experience agrees with that of Drs. Frank and his co-workers that little is to be expected from the injection of estrogenic or gonadotropic substance in the primary amenorrheas. The lack of response to the large doses they used show how utterly useless the dose usually recommended must be. I should like to ask Dr. Frank whether in his opinion the use of progesterin in addition to estrogen and the gonadotropic hormone might be indicated in those cases especially in which a normal or increased amount of estrogenic hormone in the blood is demonstrable. There is some evidence to show that the various phenomena developing during the menstrual cycle are dependent on a balance between these two hormones. Drs. Burch and his co-workers emphasized that an accurate diagnosis should be made in these patients showing menorrhagia and metrorrhagia before attempting any form of endocrine therapy. How easy it is in a woman somewhat obese to overlook a small fibroid uterus. I have found definite organic changes including carcinoma, fibromyomas, adenomyomas and polyps in uteri removed from patients previously treated over a considerable period of time with endocrine therapy. Thyroid extract is valuable in these patients with menorrhagia on a basis of hypothyroidism. I have not found it necessary in these cases to use the estrogenic hormone in addition to the thyroid. Gonadotropic substances from the urine of pregnant women or from the placenta have given some favorable results in some menorrhagia cases, but I have noted usually that these results were temporary and that progesterin preparations seemed to stop the bleeding when the other hormone failed. I have also noted in a few cases temporary improvement followed by failure after injections of progesterin. In such cases a combination of progesterin and thyroid has given good results. Thyroid deficiency as a predisposing cause of sterility is almost universally admitted. The mechanism by which this is brought about is not clear. Does the thyroid extract act directly on the ovary? Does it act on the hypophysis primarily and on the ovary secondarily, or does it act directly on the uterus? The more or less empirical use of a remedy usually precedes the scientific explanation of its action by a number of years. As regards the treatment of habitual abortion or threatened abortion by progesterin, more recent experience has confirmed my earlier clinical impression and laboratory experiments demonstrating its inhibiting action on the contractions of the human uterus reported here two years ago. There is no doubt that this is a valuable therapeutic agent. I am impressed by the careful method of control which Dr. Pratt and Dr. Thomas have adopted to avoid any semblance of prejudice on their part which might develop in favor of one or another treatment. The results are thought provoking. My experience in dealing with these menopausal cases recently has been largely confined to the use of emmenin in the liquid form. Whether the effect is produced psychologically or physiologically, I am not prepared to say, but that a higher percentage of patients get a greater degree of relief than with the sedatives and estrogenic hormone injections previously used I am firmly convinced.

DR. AUGUST A. WERNER, St. Louis. Drs. Pratt and Thomas stated that "a group of symptoms occurs that is char-

acteristic for the menopause, castration and partial castration." This is an accepted fact. These symptoms are not due to failure of ovarian function per se, they are initiated by ovarian failure. Failure of ovarian function disturbs the pituitary gland, which exercises an influence over most of the other glands of internal secretion. This secondary disturbance causes imbalance of the two divisions of the autonomic nervous system and these combined factors produce the characteristic symptoms complained of by castrates and menopausal women. The duration of the menopause in some women is from three to six months, in others the duration may be five or six years. If a woman whose glandular-autonomic stabilization will require five years is treated for three months with relief of her symptoms, it can be expected that she will have a recurrence of her symptoms at a later time, and treatment must be reinstituted from time to time until they cease to recur. Some women have mild to severe psychotic symptoms at the climacteric, and if they are sufficiently severe the condition has been termed involuntional melancholia. Drs Pratt and Thomas stated that they had kept some of these psychotic women in the hospital under treatment for as long as three months without relief. We treated forty women having involuntional melancholia (menopausal psychosis) at the St. Louis Sanitarium and at Missouri State Hospital No. 4. Twenty were given injections of theelin and twenty were administered physiologic solution of sodium chloride intramuscularly as controls. Six months' treatment was decided on arbitrarily. Within six months, 66 per cent of the theelin treated women had recovered, and those who were given physiologic solution of sodium chloride were not improved. We then treated the controls with theelin and had approximately 66 per cent recovery in that group. I cannot agree with Dr Pratt that estrogenic hormones do not help these women or that such treatment is only psychic.

DR CHARLES W. DUNN, Philadelphia. An unmentioned group of endocrine disorders, the adrenal cortical hyperplasias or tumors, are concerned in all the presentations except that of Drs Lewis and Adler. In the adrenogenital syndrome—virilism—and in basophilism the ovarian disorder accounts for the hypo-ovarian syndrome as defined by Dr Sevrinhaus. Dr Broster of London performs partial adrenalectomy in cases of adrenocortical hyperplasia, with good results in restoring menstrual function. In his cases, preoperatively, the menstrual picture varied, some had amenorrhea, others hypomenorrhea and others increased menses. Adult cases of this type show early onset of menses and menorrhagia, at 16 to 18 years of age, diminishing or abrupt cessation of menses, onset of hypertrichosis and frequently hypertension. Sterility and the hypo-ovarian syndrome are also part of adrenal cortical hyperfunction. Drs Novak and Werner pointed out that we are dealing with multihormonal disturbances. Crookes states that the pituitary pathology of basophilism (pituitary basophilic adenoma, carcinoma of adrenal cortex or thymus and arrhenoblastoma of the ovary) is a hyaline cytoplasmic change and loss of basophilic granules in the basophil cells, the presumed source of the gonadotropic fraction. Although reputed to be a hyperfunctional basophilic reaction, pathologically and clinically a subovarian state results. In such adrenal cortical disorders, Grollman believes that the pituitary changes initiate the ovarian hypofunction and in some manner stimulate the androgenic zone, which is a destructive cell area lying beneath the adrenal cortex. He believes that adrenal cortical carcinoma does not produce basophilism. This view is supported by authentic cases and one recently reported by Ullam. Patients presenting hypertrichosis, moderate hypertension and a history of sterility were treated with progesterone and pregnancy occurred. Patients simulating the Cushing type became pregnant while amenorrheic, confirming Dr Frank's observation. As early as one month after pregnancy, patients have developed an acute clinical condition of pituitary-adrenal origin, this brings forth Grollman's belief that puberty and pregnancy induce hyperplasia of the androgenic layer. In treating these cases I have to administer higher dosage of estradiol benzoate than given by Dr Frank and his co-workers. If dosage is low the symptoms are relieved but the menses are not influenced. Higher dosage not alone relieves the symptoms but also induces uterine bleeding in the amenorrheic cases.

DR JACOB HOFFMAN, Philadelphia. At the Endocrine Clinic of the Jefferson Hospital we have had the opportunity of studying more than 800 cases of functional menstrual disorders, sterility and symptomatic menopause. Endometrial biopsy as well as the sex hormone determinations of the blood and urine were used in the evaluation of these cases. An analysis of our observations reveals that these patients fall into two main groups. In one the disorder is purely functional, is capable of spontaneous correction and is amenable to treatment, in the other the condition is an expression of constitutional inferiority or a deep-seated endocrinopathy and is very resistant to any form of therapy. We have employed both general medical measures and organotherapy. Controls were used in whom the sex hormone preparations were employed. Our experience has shown that the commercial preparations have only a limited sphere of usefulness. This is not surprising, for the gonadotropic substances have not been shown to exert a stimulating effect on the human ovary, while the ovarian sex hormones, though capable of stimulating the accessory genitalia, cannot activate the ovary itself. An indirect effect of these substances by way of the anterior hypophysis has been demonstrated in the laboratory animals but not in man. The use of estrogenic preparations for the relief of menopausal symptoms has been hailed as an outstanding example of the value of sex hormone therapy. We have employed estrogen as well as nonspecific therapy consisting of hypodermic injections of saline solution together with sedatives and found the former less effective, although large doses have been administered over a long period of time. I am therefore wholly in accord with the observations of Dr Pratt and his co-workers. When it is recalled that the climacteric involves not merely a withdrawal of estrogen but also a general endocrine upheaval as well as structural alterations throughout the organism incident to the approaching senium, the beneficial effects of estrogen may well be questioned. Medical treatment yields the best and most enduring results. General hygienic measures, correction of nutritional faults and the correction or elimination of all constitutional depressive states, supplemented by thyroid extract where indicated, will favorably affect the organism as a whole and with it the gonads. Reduction of weight in the obese and an increase in weight in the thin asthenic type is often sufficient to regulate the menstrual rhythm and raise the level of fertility.

DR MISCH CASPER, Louisville, Ky. This symposium brings out some real advancement in endocrinology. Why do little girls have to have gonorrheal vaginitis? Is the first question. Why does any one have to have gonorrheal vaginitis? Why can't this humiliating and distressing disease be banished, now that so much is known about the gonococcus and gonorrhea and there really exists something to offer in the way of the cure of this disease? The medical profession has been derelict in the handling of gonorrhea in the past, but I believe now there is an awakening, because we have something in the way of treatment to get rid of this disease. I am sure that Drs Lewis and Adler, while not discussing gonorrhea generally, have no objection to using other means of treatment along with the endocrine treatment. The Elliott hot water treatment, hyperpyrexia, and later the sulfamidamide treatment have all proved effective in getting rid of gonorrhea.

DR CECIL STRIKER, Cincinnati. I should like to ask Dr Frank whether he has any fear or any evidence of malignant changes following massive doses of these hormones, and I should like to have an expression both from him and from some of the other authors.

DR PETER B. SALATICI, New Orleans. I would like to ask Dr Litzenberg whether the question of sterility in the male side of the picture was thoroughly studied.

DR JEAN PAUL PRATT, Detroit. I am grateful to the discussors for helping to emphasize some of the varied manifestations of the so-called menopause. Dr Novak emphasized the vasomotor symptoms as being outstanding, and perhaps objective symptoms. I agree in part that the hot flushes may be objective. For the most part however, they are subjective. They seem to be such an important symptom of the menopause that we did not include cases as menopausal unless the women had hot flushes, because that seems to be the one symptom on which every one agrees when they discuss the menopause. We charted

the number of flushes. We asked the patient to do the same, but we were confronted with an unscientific observer furnishing the information. Most observations of the menopause are unscientific. It is extremely difficult to set up any experiment that will correspond with the carefully controlled laboratory experiments. Dr Sevringhaus questions the term "physiologic or pathologic states." Life is a continuous process. There is a period of rapid growth in childhood, a period of continued rapid growth in adolescence. Then there is a flattening of the curve during the reproductive period, following which the curve trends downward to senility. Somewhere along that curve occurs the first conspicuous event of the reproductive life, namely, the first menstruation. In the mind of the public the first menstruation is puberty, but physicians know that puberty extends over a long period. The same is true of the menopause. The public is firmly convinced that cessation of menstruation is the menopause, but physicians know differently. It is a very gradual change. The function of the ovaries trends downward for a period of several years. That is what I mean by a physiologic state. It is not a sudden change in the state of the ovaries. It is a gradual process which has been going on for years. The question of the use of large doses of estrogens has been very kindly answered by Dr Hoffman. Dr Werner insists on keeping the psychoses in the group of menopausal symptoms. I am sorry that I cannot give the statistics furnished by the superintendent of a large institution for the insane, who told me that the expectancies of the psychoses of that type were no greater in relation to the menopause than they were at any other time in the individual's life, so that the justification for calling the psychosis menopausal is not borne out by statistics. We do not mean to imply that the menopause cannot be cured by the estrogenic hormones. Fortunately, they can cure, as well as almost anything else. It does not make so much difference in the large proportion of cases what agent is used. We were trying to determine what particular patients had evidence of ovarian failure and reserved estrogenic therapy for that particular group. The 85 per cent who go through the menopause without any particular disturbance keep most of the menopausal women from seeking medical aid, so we probably are dealing with only 15 per cent. Of that 15 per cent we found that 75 per cent were relieved by almost any form of therapy. Probably in the small group remaining it will be found that there is a definite need for some specific therapy.

DR JENNINGS C LITZENBERG, Minneapolis. The question was asked whether anything had been done about the male studies. I was discussing one subject only, and that is the endocrine influence on the female. It goes without saying that every one of these patients was studied thoroughly from every other standpoint, which always should be done with every sterile couple before taking up the endocrine studies. The thorough study of the husband as well as of the wife was made in every case of sterility. One should not study individual sterility alone but should approach the question as pair sterility. Any one who attempts to treat sterility without studying the male as well as the female, of course, is not doing his duty.

DR MORRIS A GOLDBERGER, New York. In our bio-assay and treatment of amenorrhea, only functional cases of amenorrhea were studied. Cases in which there were severe endocrine disturbances were omitted. The animal response to extracts from human beings is not positive proof that the substances obtained are definite causative factors in the production of symptoms in the human being. Our hormone bio-assays have shown that cases of amenorrhea fall into four groups: the acyclic type, the subthreshold type, the normal type and the polyhormonal type of Zondek. The presence of gonadotropic factors, or an absence of them, may be found in any of these groups. The response of the menopause patient to 30,000 rat units as viewed objectively, consists in the disappearance of the gonadotropic factors from the urine, and the change in the vaginal smear. The patient is instructed how to prepare the smear, and when obtained they are brought to our laboratory, where they are stained with 1 per cent aqueous fuchsin. A change in the smear occurs corresponding to that in the rodent and consisting in the replacement of the leukocytes by small epithelial cells, even to complete squamous cell metaplasia. These effects are definitely noticed in the menopause, and those cases of amenorrhea which respond in this way are taken out

of the functional amenorrhea group and placed in the menopausal group. Dr Novak stressed the use of serial endometrial biopsies. We have done this in several of our cases but as yet have not fully correlated the results obtained with our bio-assays. Another point Dr Novak mentioned that we also stress is that the uterus in our amenorrhea cases appears to be refractory to treatment with hormones. We agree with Dr Sevringhaus that we do not as yet know whether or not the hormone assays are quantitatively and qualitatively the same. To Dr Fall's question of the use of progestin in addition to estrogen in the treatment of amenorrhea we can only say that, were it to be used, a definite change in the endometrial picture to one resembling more nearly the normal premenstrual endometrium would be obtained. Bleeding may take place, but the cost of treatment would be doubled, since approximately 35,000 rabbit units of progestin is necessary. Besides, in the long run the patient would not be appreciably benefited because, in order to insure a continuation of the menstrual function, treatment would have to be prolonged. In answer to Dr Striker, whose question concerns the fear of the use of large doses of estrogenic preparations, I may say that in adults we have never experienced any untoward effects or any changes suggesting malignancy. Bleeding, however, has been obtained. On the other hand, in prescribing gonadotropic substances, especially the newer products made from horse serum and available in high concentrations, care must be exercised in their use because of the proteins present, to which many individuals may be sensitized. When these substances are used, we invariably test for sensitivity intradermally.

A NEW DIAGNOSTIC INTRADERMAL REACTION WITH BOWEL ANTIGEN

INDICATING THE PRESENCE OF THE VIRUS OF
VENEREAL LYMPHOGRANULOMA IN THE
INTESTINE AND DIFFERENTIATING
COLITIS ASSOCIATED WITH
THAT VIRUS

MOSES PAULSON, M.D.

WITH THE TECHNICAL ASSISTANCE OF BETTY KRAVETZ
BALTIMORE

Idiopathic or nonspecific ulcerative colitis is an involvement of the large intestine, regional or general, of unknown etiology, resulting in an exudate of, or feces containing, blood, mucoblood or pus, or all of them. There was reason to believe that in some cases colitis with or without a stricture might be due to a virus. If this were proved, a virus as a factor in intestinal disease would come into being, and the classification idiopathic ulcerative colitis would be narrowed.

The first step in attempting to demonstrate colitis associated with virus rests, if not in the actual isolation, at least in the indication of the presence of such an agent directly from the region of suspected colonic involvement.

Patients with ulcerative colitis of indeterminate etiology were selected in whom the possible presence of a virus in the colon might be related to the colitis as suggested by their having a positive intradermal response to inactivated hubeo pus due to the virus of

From the Gastro-Intestinal Section and Laboratories of the Medical Clinic of the Johns Hopkins Hospital and the Johns Hopkins School of Medicine.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

The following cooperated: Drs Harry M Robinson, Baltimore, and Harry B Burr, Houston, Texas, sent generous supplies of hubeo pus. Drs George W Binkley and H N Cole, Cleveland, Robert B Greenblatt and Everett S Sanderson, Augusta, Ga., George A Hunt, St. Louis, Collier F Martin, Philadelphia, and Marion B Sulzberger, New York, Margaret Johnson and Ethel H Bohanan of the Social Service Department of the Johns Hopkins Hospital assembled cases.

venereal lymphogranuloma (Frei reaction and Frei antigen, respectively) In this connection, it must be recognized that a positive reaction to the Frei test associated with otherwise unexplained ulcerative colitis does not of itself prove that the virus of venereal lymphogranuloma is etiologically related to the colitis, it is conceivable that a colitis might not bear any relation to antecedent, simple, uncomplicated and healed venereal lymphogranuloma or to coinciding venereal lymphogranuloma

It was hypothesized that if antigens could be prepared from bowel material from patients with ulcerative colitis which would give reactions comparable with known positive and negative reactions to Frei antigen (diluted inactivated bubo pus), a positive intradermal response with the bowel antigen would indicate the presence of a specific antigenic substance, either the virus of venereal lymphogranuloma or an associated product—nonspecific or otherwise but acting in a specific manner—in the intestinal contents from which the antigen was made

I have already reported¹ the striking intracutaneous responses with bowel antigens from three patients with ulcerative colitis with positive reactions to the Frei test. Reactions of 5 mm or more in diameter persisted for at least nine days in six patients with ulcerative colitis and positive Frei reactions, negative reactions with these antigens were encountered in at least twelve of thirteen control patients with and without colitis and with negative Frei reactions. This indication of the presence of virus was incomplete owing to technical difficulties in the preparation of bowel antigen. As a result, no control studies could be undertaken on persons without colitis but with positive Frei reactions. Also because of technical difficulties, control studies with bowel antigens, particularly from patients with ulcerative colitis and negative Frei reactions, could not be done.

This communication reports a new technic making possible the practical preparation of bowel antigen and the results of studies with additional bowel antigens, including the necessary control studies referred to. The following data establish, it is believed, a practical intradermal diagnostic method with bowel antigen to indicate the presence of the virus of venereal lymphogranuloma or an associated product in the human intestine, as well as a means of differentiating colitis associated with the virus of venereal lymphogranuloma.

PROCEDURE

A Preparation of Patient—1 Two enemas of physiologic solution of sodium chloride are given, one at bedtime and the other on the following morning a few hours before the rectosigmoidoscopic examination. The purpose is to prevent gross fecal contamination.

B Securing of Material—1 Devices employed (a) A rectosigmoidoscope 1 cm (three-eighths inch) or 1.6 cm (five-eighths inch) in diameter and 25 cm (10 inches) in length is employed, depending on the presence and size of the stricture. An instrument smaller than 1 cm in diameter does not allow adequate vision and satisfactory insertion of the aspirator. This aspirator is of metal and measures 35 cm by 8 mm. These are sterilized by boiling. A suction apparatus is also needed.

(b) The receptacle is a glass tube, 15 cm (6 inches) high by 2.5 cm (1 inch) in diameter, containing fifteen glass beads. The rubber stopper, glass and rubber connections (fig 1) are sterilized in the autoclave.

2 Method The material, which is usually mucopurulent, frequently bloody, but grossly free from fecal matter, is aspirated by suction into the glass tube containing beads. The prime object is to secure it undiluted and measurable in order to make accurate antigen dilutions, thus, to 1 cc of the material, 10 cc of a diluent (azochloramid, to be referred to later) is added. This is called a 1 to 10 dilution. In most instances this is not possible, for either there is too little exudate or it is very tenacious, too thick or, sometimes, not visible. Under such circumstances 5 cc of the diluent is poured through the rectosigmoidoscope and then quickly aspirated.

Aspirated material is vigorously agitated so as to be well mixed and to be broken up into smaller particles.

Whenever dilution in vivo becomes necessary, the subsequent dilutions in vitro in the preparation of

Fig 1—Device for collecting material for antigen from the bowel through the rectosigmoidoscope

antigen become arbitrary, since standardization by weight or volume is impossible, however, the same criteria, to be noted, are employed throughout. Whenever the material is too thick to be readily drawn into a sterile calibrated 10 cc pipet, it is treated as undiluted and to each cubic centimeter 9 cc of the diluent is added. It is arbitrarily designated as a 1 in 10 dilution. Material of "medium" consistency is that which can be drawn into a sterile calibrated 10 cc pipet with facility. Usually, from 3 cc to 5 cc of this material is obtained. The diluent is added to make a total volume of 10 cc.

Not infrequently, the aspirated material obtained after the addition of the azochloramid through the rectosigmoidoscope is very thin and translucent, contains little bowel exudate and is mostly diluent. In this case no further dilution is made.

It is to be emphasized that the dilutions are actually higher than indicated, since sodium sulfite and merthiolate—as will be noted—are added.

C Preparation of Antigen—I have already reported¹ the inability to demonstrate the presence of a reaction-producing substance either in filtered bubo pus, a portion of which when unfiltered produces a positive Frei

1 Paulson Moses: Intracutaneous Responses Comparable to Positive Frei Reactions with Colonic Exudate from Chronic Ulcerative Colitis Cases with Positive Frei Tests. *Am J Digest Dis & Nutrition* 3: 667-673 (Nov.) 1936.

reaction, or in filtered bowel material. Thus, the problem in the preparation of bowel antigen concerns itself with the destruction of bacteria without disturbance of the possible antigenic factor and with dilution of the material sufficient to decrease foreign protein, so as not to mask the intradermal reaction, and yet insufficient to eliminate for practical purposes the antigenic factor. Also, heating at 60 C for two hours on one day and one hour on the following day, even in the presence of the bactericidal and bacteriostatic action of the antigen diluent—azochloramid—will not always result in complete bacterial destruction. A higher temperature at 80 C for one hour is also employed, since I have learned that the antigenic product in bubo pus due to venereal lymphogranuloma will withstand higher temperatures.

The heating is accomplished in the following manner so that at least one antigen will be obtained from a given patient suitable for use in the face of the difficulties referred to.

Equal portions of the material aspirated from the bowel through the rectosigmoidoscope, with or without

viving both the original supply of azochloramid and the first heating, while making the final dilution no higher than that of the previous antigens.

Vial D The contents are diluted with half the amount of azochloramid used in vials A and B, and the vial is sealed and left at room temperature over night. Then it is heated at 80 C for one hour, after which the remaining half of azochloramid is added.

Not infrequently, the material obtained through the rectosigmoidoscope after the necessary addition of 5 cc. of azochloramid is thin, translucent instead of opaque, contains little bowel exudate and is mostly diluent. Equal portions of this material—without further dilution—are placed in two vials. One is heated at 60 C for two hours and for one hour the following day. The other is left at room temperature and on the following day is heated at 80 C for one hour.

In order to dechlorinate the antigens to eliminate the irritating dermal properties and to avoid the carrying over of free chlorine to the sterility test medium, the following procedure is carried out. To azochloramid solution (1:1,666) equivalent to the amount in the vial

the addition of 5 cc. of azochloramid, are placed in four sterile 5 or 10 cc. No. 12 army vaccine vials.

Vial A The contents are diluted either 1 in 10 or 1 to 10 with azochloramid, as already indicated. The vial is sealed with a rubber stopper and collodion and heated in a water bath at 60 C for two hours, left at room temperature over night and on the following day heated at 60 C for one hour.

Vial B The contents are identically diluted and sealed, but the vial is left at room temperature over night to insure the complete action of azochloramid, which is modified by the higher temperature of 80 C for one hour to which the vial is submitted on the following day.

Vial C The contents are diluted with half the amount of azochloramid used in vials A and B, and the vial is sealed and heated at 60 C for two hours. Then by means of a sterile needle and syringe, the other half of the diluent is added. This vial remains over night at room temperature and on the following day is heated at 60 C for one hour. The purpose is to supply fresh bactericidal action on organisms sur-

to be dechlorinated, a sterile, fresh 10 per cent aqueous solution of sodium sulfite is added until the yellow color completely disappears. An equal amount of the sulfite is added to the antigen.

Sterility tests then follow. 0.1 cc. of antigen is placed in 5 cc. of infusion bouillon and incubated aerobically, and 0.1 cc. is inoculated in anaerobic cooked meat medium. The cultures are incubated for seven days. A deep blood agar pour plate is then inoculated with 1 cc. of infusion bouillon culture and incubated aerobically. An anaerobic plate is inoculated with an identical amount from the cooked meat culture, if it is not obviously contaminated, and incubated anaerobically. The plates are incubated for four days.

Merthiolate (1:10,000) is added to each vial immediately after the medium for sterility tests has been inoculated. Not until sterility tests are satisfactorily completed are antigens ready for use.

My experience has been that of the four antigens prepared as outlined in each case, at least one is satisfactory. It is to be reemphasized that this result can be consistently accomplished only by the avoidance of gross fecal contamination.

Although no differences have been noted with antigens heated at the varying temperatures and for the durations noted, I have preferred to employ those prepared at 60 C when obtainable

THE DILUENT AZOCHLORAMID

Without the use of azochloramid this work might not have been accomplished. My earlier experience established that the preparation of satisfactory bowel antigen was a fortuitous circumstance since it was impossible to predict when with identical technic another antigen would become available. In most instances the heat used to inactivate the possible virus or inciting substance prior to intradermal inoculation was insufficient to destroy all the intestinal bacteria. I have found that azochloramid destroys all types of intestinal bacteria both aerobic and anaerobic in tremendous numbers in dilutions which on the addition of sodium sulfite, will give no intradermal reactions. I have found that it will not destroy the antigenic substance in bubo pus due to the virus of venereal lymphogranuloma or the inciting agent in bowel material. Its action will not be disturbed at 60 C and can be checked immediately by the addition of sodium sulfite as noted. This new chlorine compound of unusual properties was introduced by F C Schmelkes in 1934.

SOURCES AND TYPES OF ANTIGENS

- Type I Patients presenting a positive Frei reaction and ulcerative colitis with or without stricture but no elephantiasis or vegetations. They have been subdivided in the master chart (table 1) as A and B, the bowel exudate of the former having proved to contain the antigenic factor and that of the latter having it weakly or not at all.
- Type II Patient presenting a negative Frei reaction (to five active Frei antigens) but a strongly suggestive history and a striking clinical picture of venereal lymphogranuloma with colitis and stricture.
- Type III Subject presenting a positive Frei reaction without any disorder of the bowel (control).
- Type IV Patients presenting a negative venereal lymphogranuloma history, a negative Frei reaction and ulcerative colitis with or without stricture (controls).
- Type V Patient presenting a positive Frei reaction and ulcerative colitis; the antigen having been prepared from material obtained by ileostomy (control).

SUBJECTS ON WHOM ANTIGENS WERE TESTED

Intradermal reactions with these antigens were tested in four types of cases—those presenting positive and those presenting negative Frei reactions with and without colitis.

INTRADERMAL REACTIONS AND INTERPRETATIONS

One-tenth cc of the bowel antigen is injected intradermally as is the Frei antigen several specimens of which are tested simultaneously on each patient for comparative purposes. The results are read at nine or ten days. A reaction with either the Frei or the bowel antigen is considered positive only if its diameter is at least 5 mm. Induration is found more often than papule formation with or without necrosis; induration may extend beyond papule formation. Erythema extending beyond induration and papule

formation or any skin scarification or pigmentation, is not considered in measurement. Induration and papule formation are the bases of measurement.

SUBJECTS ON WHOM ANTIGENS ARE TO BE TESTED FOR INDICATION OF THE VIRUS OF VENEREAL LYMPHOGRANULOMA IN THE BOWEL

Three patients known to have a positive reaction to at least one satisfactory Frei antigen and three without a history or evidence of venereal lymphogranuloma and with a negative reaction to multiple active Frei antigens, neither group manifesting any active systemic disorder or any organic gastro-intestinal disease are to be inoculated intradermally with the bowel antigen to be tested in the manner already indicated. Multiple Frei tests should be repeated simultaneously whenever possible for comparative purposes. The criteria deter-

Fig 2—Examples of intradermal responses to bowel antigens. Colored woman with ulcerative colitis, stricture and a positive Frei reaction. Responses were measured at nine days. 2 and 3 are positive reactions to a bowel antigen included in type 1A, both were diluted 1:20; the diluent of the first being azochloramid and the second physiologic solution of sodium chloride. No differences were noted. 4, 9 and 10 are negative reactions to bowel antigens included in type 1B. 8 is the negative reaction to antigen prepared from normal ileal material (type V). 5, 6 and 7 are positive reactions to the antigen prepared from the involved distal colon of the same case (included in type 1A). 5 is a 1:10 and 7 is a 1:20 dilution in physiologic solution of sodium chloride and 6 is a 1:20 dilution in azochloramid. 11 is a positive response to type II antigen. 12 is the positive response to 1:5 dilution of inactivated bubo pus (Frei reaction and Frei antigen respectively).

mining the responses to both Frei and bowel antigens are identical and have been outlined in detail. The testing will be facilitated by the maintenance of an up-to-date list not unlike that of blood donors, of persons who meet the foregoing requirements and who are readily available and cooperative. They can be secured from among the hospital staff, employees and patients.

TERMINOLOGY

To avoid confusion in designation and to distinguish the bowel antigen and its intradermal response from the Frei antigen and its reaction the following terminology

Schmelkes, F. C. and Mark, H. C. N. Dichloroazo-dichloroamine (Azochloramid) and N-Chloro Derivative of the Oxidant in an Oxidation-Reduction System. J. Am. Chem. Soc. 56: 1610-1612, 1934.

is suggested. An antigen prepared from bowel material or tissue and its intradermal reaction should be termed "bowel antigen" and "positive (or negative) intradermal reaction to bowel antigen," respectively.

RESULTS AND INTERPRETATIONS

The master chart (table 1) is a tabulation of raw data secured by the use of twenty-four test antigens of five already described types on fifty-eight patients totaling 409 intradermal tests. Tables 2 and 3 are contractions of data derived from the master chart and presented for further clarity and to emphasize certain important points.

Table 2 shows first the intradermal reactions to all bowel antigens in persons with positive and with negative Frei reactions, without any regard to the question of accompanying colitis. However, in order to show the influence on the dermal reaction of the presence or absence of accompanying colitis—with or without stricture—in those on whom the bowel antigens were tested, subdivisions of each group have been constructed.

with control bowel antigens would not seem to indicate the presence of virus, since those having a positive Frei reaction and no colitis react less often than those having a positive Frei reaction and colitis. Also, when control antigens are tested on those with and without colitis regardless of the Frei reaction, the percentage of positives in these two groups is not significantly dissimilar statistically (table 3). However, the numbers tested may be too small to make definite deductions.

The comparative intradermal reactivity produced by active bowel (types IA and II) and active Frei antigens is more striking than the figures indicate, when the following differences in these antigens are considered. The Frei antigen consists of uncontaminated and undiluted bubo pus, relatively concentrated because of the circumscribed area of involvement. Subsequently it is diluted, usually 1 to 5, prior to inactivation and use. On the other hand, the bowel antigen is secured from material diluted by contaminating bacteria, blood, mucus, pus and intestinal contents. Frequently, the antigenic material is further reduced by an accompany-

* Figures in parentheses represent totals.

Six positive antigens (types IA and II) were realized from twelve suspected sources.

It is to be noted that reactions to bowel antigens possessing strong reaction-producing substances (types IA and II) paralleled the positive Frei reactions in 86.5 per cent of instances when the question of colitis was not considered. These bowel antigens gave falsely positive results slightly in excess of 1 per cent. However, differences were to be noted in the groups with and without colitis when the same antigens were used. The reactions paralleled those to the Frei test in 93.4 per cent and 76.9 per cent, respectively. False positive reactions totaled 2.4 per cent in the former and were absent in the latter. Similar differences were noted with control antigens (types III, IV and V), false positive reactions occurring in 16.7 per cent of cases with positive Frei reactions and 3.2 per cent in those with negative Frei reactions. However, 33.3 per cent of the patients with colitis and 13.3 per cent of those without colitis, and with positive Frei reactions, and 1.8 per cent and 4.4 per cent of those with and without colitis, respectively, and with negative Frei reactions gave false positive results (table 2). These differences in the response to control bowel antigens cannot be satisfactorily explained. They are probably not due to a non-specific substance in bowel antigens from colitis cases to which a patient with any type of colitis may react, since those having a negative Frei reaction and colitis did not respond as frequently as those having a positive Frei reaction and colitis. Positive reactions

ing dysentery. In preparations of bowel antigen—because of the possible masking of the intradermal reaction by a reaction to foreign protein—the material is still further diluted at least 1 in 10. Several of these antigens have given positive responses when diluted 1 to 20, 1 to 40 and 1 to 80.

The relative closeness in the incidence of intradermal reactions caused by suitable types of both bowel and Frei antigens, in white and Negro males and female

with and without colitis, the identicalness of their responses persisting at the end of nine or ten days in papule formation or induration of a minimum diameter in any direction of 5 mm, indicates an antigen factor common to the two antigens. This factor is believed to be the inactivated virus of venereal lymphogranuloma or some accompanying product—non-specific or otherwise—acting in a specific manner. Thus a positive intradermal response, under the conditions already set forth particularly when interpreted with the clinical

picture, indicates the presence of virus in the bowel of the person from whose intestinal material the antigen was prepared. A negative reaction may indicate either the absence of such a product or its presence in too small an amount to be shown by this method. It is to be added that these intradermal responses to antigens of unfiltered bowel material prepared in consequence of filtration obstacles cannot be considered as due to bacteria or foreign protein. The sources of the antigens gave a negative response to the Ducrey bacillus vaccine indicating the probable past and present absence of infection due to that bacillus. Gonococci, the causative organisms of syphilis and chancroid tubercle bacilli, nonpathogenic and pathogenic intestinal bacteria, toxins or a foreign protein are not known to cause responses of this nature. Thus it is believed that a practical method has been devised despite its crudity of indicating the presence of the virus of venereal lymphogranuloma in the intestine.

This method can be used also in differentiating colitis in which there is indication of the virus of venereal lymphogranuloma from those in which there is not. Thus the classification ulcerative colitis, which probably includes some cases of colitis accompanied by the virus, can be further narrowed. Besides another approach in management becomes possible for the patients manifesting the virus in the bowel. The importance of the clinical use of bowel antigen tests in the following. The possible contracting of this disease not always through venery its striking incidence as reported by Gray and Hunt³ and by D'Aunoy and von Hamm⁴ its protean manifestations and the probable greater frequency of venereal lymphogranuloma in the white race in this country than is generally recognized, lead to the belief that colitis associated with this virus may not be so rare as has been thought. While the indication of the presence of the virus of venereal lymphogranuloma in the bowel is not proof of etiology of the colitis which it accompanies experimental and clinical evidence strongly suggests this relationship. Differentiation of colitis by the clinical picture or the positive or negative Frei test alone is inadequate. For instance, a white man with a clinical picture of venereal lymphogranuloma of nine years duration had a negative reaction to five human Frei antigens. His bowel antigen (type II antigen) gave eight positive and five negative responses in thirteen patients with positive Frei reactions and twenty-three negative reactions in twenty-three patients with negative Frei reactions. Also non-specific ulcerative colitis with indications of accompanying virus of venereal lymphogranuloma may be indistinguishable clinically from ulcerative colitis without such evidence. As an example in the case of a Negro woman with a positive Frei reaction and otherwise clinically indistinguishable ulcerative colitis (without stricture) the reactions to antigen prepared from her intestinal material paralleled positive and negative Frei reactions. Also, a few patients with non-specific ulcerative colitis not associated with the virus of venereal lymphogranuloma and negative Frei reactions have been followed over years stricture formation occurring during observation, yet in many respects their condition is not always to be clearly differentiated clinically from that of persons regarded as presenting characteristic colonic venereal lympho-

granuloma. The positive Frei reaction may not be particularly helpful, because the colitis may bear no relation to antedated and hereditary venereal lymphogranuloma and does not indicate such virus presence in the bowel.

The significance of bowel antigen is further indicated by the fact that from a white woman with a positive Frei reaction in whom an ileostomy had been performed for the relief of ulcerative colitis (and stricture) a positive antigen (included in type I) was procurable from the involved distal colon, and a negative antigen (type V) from the normal ileum.

The accuracy of the test as a diagnostic method in indicating the presence of virus in the bowel is based on experience with 409 intradermal tests with twenty-

Fig 3—Examples of intradermal responses to bowel antigens. White man with ulcerative colitis and negative Frei reaction (control case). These responses were measured at nine days. All were negative. 1 and 11 are reactions to positive bowel antigens; the former is included in the type I A group and the latter is type II antigen. 2, 4 and 5 are reactions to negative bowel antigens included in type I B. 3 is a response to the type V antigen (control). 6, 8, 9 and 10 are reactions to antigens included in type IV (control).

four antigens on fifty-eight persons. On this basis if antigens are procured only from patients presenting colitis and a positive Frei reaction, or from patients with colitis giving a striking history or a clinical picture highly suggestive of venereal lymphogranuloma, even without a positive Frei reaction the percentage of false positive reactions with antigens like types I and II is anticipated to be in the general magnitude of 1 per cent and 28 per cent respectively. Antigens prepared from sources such as the control group (types III, IV and V) when tested on those with ulcerative colitis and a positive Frei reaction may present 33.3 per cent false positive reactions, however when tested on healthy noncolitis subjects as recommended the percentage of false positive reactions may be about 13.3 per cent in the cases with positive Frei and 4.4 per cent in those with negative Frei reactions (table 2). It is hoped that refinements in antigen preparation will result in fewer false positive reactions.

SUMMARY AND CONCLUSIONS

A technic has been evolved for the practical preparation of a bowel antigen for intradermal use. A positive response to the antigen indicates the presence of the virus of venereal lymphogranuloma in the material from which the antigen was made. While the indication of the presence of the virus of venereal lymphogranuloma in the bowel is not proof of etiology of the colitis which it accompanies, experimental and clinical evidence strongly suggests this relationship.

Criteria for interpretation of the intradermal tests have been developed.

By tests with this antigen it is hoped to narrow further the classification nonspecific ulcerative colitis, the cases in which there are indications of the virus of venereal lymphogranuloma in the intestine being separated from those in which there are not, suggesting differences in clinical approach.

Medical Arts Building

ABSTRACT OF DISCUSSION

DR IRVING GRAY, Brooklyn. Dr Paulson's studies would indicate that in some patients with ulcerative colitis a virus may be the responsible, activating factor in the disease. He has described a new technic making possible the practical preparation of bowel antigens and has further established a method whereby it is possible to differentiate colon infection associated with or perhaps due to virus infection. Evidence that an antigen in some cases of colitis behaves like a Frei antigen is strongly suggestive. It is evident that where the Frei test is negative in tested patients virtually no positive reactions may be expected with bowel antigens regardless of the source. In those patients in whom the Frei test is positive and colitis is present, a high percentage of positive reactions may be expected. In those in whom the Frei test is positive and colitis is absent, less positive reactions were obtained. Among the subjects tested, it appears that a positive or negative Frei reaction was the deciding factor rather than presence or absence of colitis. If the bowel antigen was obtained from a Frei-positive patient, a higher percentage of positive reactions could be expected, irrespective of whether or not the subjects tested had colitis. The virus of venereal lymphogranuloma is not known but the lymphotropic tendencies and the clinical manifestations of the disease are recognized. Since ulcerative colitis and venereal lymphogranuloma are clinically and pathologically different, the questions raised by Dr Necheles, when Dr Paulson presented earlier studies on the subject are pertinent. "Can one produce colitis with virus of venereal lymphogranuloma and can material from the colon of persons with colitis and positive Frei reaction cause venereal lymphogranuloma in man and encephalitis in animals?" I should like to ask Dr Paulson to interpret the significance of the results in the type IV group. The high percentage of positive reactions with bowel antigen from a patient with ulcerative colitis with negative Frei reaction is rather striking. It is not quite clear why Dr Paulson assumes that type I-b is the result of a quantitative factor and not a qualitative one. May I inquire whether the clinical course and the sigmoidoscopic observations were in any way unusual? Was any special type of therapy instituted? Dr Paulson is to be congratulated on his interesting and stimulating presentation. He is taking a conservative attitude and not claiming an absolute identity, as there are several exceptions yet to be explained.

DR MOSES PAULSON, Baltimore. While at present it may not be possible to say that a particular bowel antigen from a control case giving intradermal reactions comparable to positive Frei reactions may not have possessed a reaction producing substance indicative of virus present in the bowel material from which the antigen was made, viewing the situation as a whole this appears unlikely. As has been pointed out, positive reactions with control bowel antigens occur less often in those having a positive Frei reaction and no colitis than in those having a positive Frei reaction and colitis. Such responses

seem not to be due to a nonspecific substance in bowel antigen from cases of colitis to which a patient with any type of colitis may react, since those with a negative Frei reaction and colitis do not respond as frequently as those having a positive reaction and colitis. I believe that the difficulties referred to arise from the crudity of the antigen which contains blood, mucous, bacteria and grossly fecal-free intestinal contents. The consequent false positive responses with control bowel antigens and subsequent problems present no greater difficulties than those encountered with other prevailing diagnostic procedures when first employed, before wide experience and refinement took place resulting in improvements. It is anticipated that improvements in bowel antigen preparation and further use will also improve its accuracy. The fact remains that the response and the ability of relatively adequate interpretation under the conditions set forth in spite of bowel antigen crudity is striking. It is to be emphasized that not all the patients from whom positive bowel antigens were secured had strictures, but all had an ulcerative colitis extending into the sigmoid as observed by rectosigmoidoscopy. The problem of therapy was not studied although there appears to be no reason why bowel antigen cannot be used for this purpose whenever the Frei antigen is and in the same manner.

OBSTRUCTIVE EMPHYSEMA AND
ATELECTASIS IN INFLUENZA

WILLIAM SNOW, MD

Director of the Department of Roentgenology, Harlem and
Bronx Hospitals

AND

CHARLES S B CASSASA, MD

Director of the Department of Surgery, Harlem Hospital
NEW YORK

We have reported in the past obstructive emphysema and atelectasis in acute respiratory disease of infants.¹ We believe that the same reactions take place in influenza and offer a rational explanation for the dynamics of the pathologic changes, x-ray appearance and clinical course. Our work is based mainly on x-ray studies over a period of years at Harlem Hospital, where annually more than 500 cases of pneumonia are seen from Dr J G M Bullowa's service alone. As far as we have been able to determine W G MacCallum is the only one in this country who has promulgated such a theory, which he based on observations made at autopsy.

PATHOLOGY

The presence of emphysema of the lungs in influenza was recognized by pathologists for many years, especially during the World War.

Wolbach² described in 1919 a striking emphysema of the alveoli best seen under the pleura. At times this leads to interstitial emphysema of the lung, mediastinum and subcutaneous tissues of the neck. We have likewise seen this and, in addition spontaneous pneumothorax in pneumonia, which we believe to be due to obstructive emphysema of the lung with rupture into the pleura.

Blake and Cecil³ noted evidence of emphysema of the lungs when they experimentally produced what they considered to be influenza in monkeys.

Read before the Section on Radiology at the Eighty-Eighth Session of the American Medical Association, Atlantic City, N. J., 10 1937.

Holt⁴ reported emphysema to be almost universally present at autopsy in bronchopneumonia of infants. He regarded it as compensatory, however.

MacCallum,⁵ in his textbook of pathology in 1920, not only recognized the presence of emphysema in influenzal bronchopneumonia but also called attention to the presence of atelectasis. Moreover, he believed that both were caused by partial or complete occlusion in the bronchial tree. Coryllos⁶ has been a most outstanding proponent in the advancement of the principle of atelectasis in pneumonia as of cardinal importance, the first stage being catarrhal, at which time the bronchi become plugged with a thick sticky secretion, which then results in atelectasis.

Fig. 1—Bronchopneumonia with marked obstructive emphysema causing displacement of the mediastinum into the opposite side of the chest.

Adami, in the "Medical History of the War," emphasized that the one invariable lesion encountered in the fatal cases of influenza in 1918 was a tracheobronchitis involving the region of bifurcation of the trachea. This spread both upward and downward into the main bronchi and their ramifications. The walls were intensely congested, of a purplish color with a grayish purulent exudate which could easily be wiped away. We believe that such a condition favors the development of obstructions in the bronchi.

It was from our x-ray studies of infants' chests that we first were impressed with the belief that obstructive emphysema and atelectasis were of importance in acute respiratory disease. In reviewing our experience with pathologic material we began to recognize changes parallel to those disclosed by x-ray study. At autopsy we found in the main the emphysema of the lungs anteriorly and the solid portions posteriorly. Most of the solid portions were not pneumonic because they could be inflated by blowing up the communicating bronchi which proved that they were atelectatic instead. Since the acutely ill infant is kept lying on his back secretions in the bronchial tree tend to gravitate posteriorly. This causes complete block followed by atelectasis. Less secretions are present in the bronchi anteriorly but they are sufficient to block the small bronchi only during expiration. As a result air gets into the alveoli and cannot get out giving an obstructive emphysema. The distribution of atelectasis and emphysema is not constant.

X-RAY EXAMINATION

Obstructive emphysema in infants as seen on x-ray examination usually involves a good portion of the

lobe and causes marked displacements. However, in an adult the same size bronchus reaches only a small portion of the lung. The larger bronchi are less likely to be involved in this process, so that in studying a film one cannot as a rule expect to find evidence of emphysema by displacements. Instead, one may be able to demonstrate small rounded dark zones usually from 1 to 3 cm in diameter. This is by no means an easy matter.

The x-ray appearances in the chest with influenza have been confusing. Sainte⁷ has given a very lucid description of the types of consolidation or density seen by x-ray study in influenzal bronchopneumonia from the mildest to the severest forms. Some cases show extensive confluent bilateral areas of density of the lung. The picture cannot be differentiated per se from acute pulmonary edema or bronchopneumonic tuberculosis. It is difficult to state whether these dense zones are atelectatic or pneumonic or both. The fact that they are often atelectatic can be inferred by the narrowing of the intercostal spaces, displacement of the mediastinum toward the affected side, and elevation of the diaphragm. If the interlobar pleura is thickened atelectasis will cause the line seen on the film to be curved, with the convexity toward the involvement. Emphysematous zones may be seen contrasted against the nonaerated. These may be mistaken for tuberculous cavities or bronchiectasis.

Other films show perhaps a few patches of density at the bases to which the roentgenologist hesitates to call attention, because he not infrequently sees the same changes without any apparent clinical acute illness. It is our belief that the lung which appears aerated requires special attention, because it may be involved with an obstructive emphysema. This is particularly true, in our opinion, when the patient shows marked evidence of anoxemia.

The secondary invaders, pneumococcus type III and the Friedlander bacillus in particular, tend to aggravate the obstructive phenomena, both emphysema and atelectasis, because they produce a very sticky and tenacious exudate. In some of these cases we have seen whole lobes involved in emphysema. Unless the roentgenologist knows the history the picture may be deceiving and strongly resemble the changes brought on by aspirated foreign bodies, described by Manges,⁸ Jackson⁹ and Spencer.¹⁰

Fig. 2—Influenzal bronchopneumonia. Right middle lobe shows obstructive emphysema. Pressure developed in this lobe is so great that it forces the interlobar fissure upward.

One of our cases of influenza showed obstructive emphysema of the right lobe, which disappeared when the patient recovered.

CLINICAL OBSERVATIONS

In the light of the pathologic and x-ray studies that have been presented, the symptoms and physical signs may be more rationally fitted into the picture. Only a few points will be mentioned.

In the presence of influenza, cyanosis and dyspnea would indicate that obstruction to the bronchial tree is taking place. This may be far out of proportion to the extent of the elicited dulness. In such cases obstructive emphysema may be dominant. The x-ray study can be very misleading if a few patches of density alone are blamed.

Scattered patches of lung density may give no physical signs of dulness because of the interspersed emphysema. This was brought out by Wessler and Jach⁹ in their discussion of bronchopneumonia in children.

It is very likely that the tympanic note heard above a consolidated zone is not due to relaxation of the lung, as has been suggested in the past, but rather to adjacent obstructive emphysema.

Clinically the patches of dulness are known to appear and disappear quickly in different zones. It has been very disconcerting to those who were not aware of this.

Fig. 3.—Influenzal bronchopneumonia. Patchy density due to atelectasis. Adjacent rounded aerated zones due to obstructive emphysema resembling bronchiectasis or tuberculous cavitation.

One of our colleagues, Dr. Emil Koffler, likes to tell the story that during the war epidemic he insisted on examining his patients in conjunction with the consultant because he knew that if he reported the physical signs of the previous day they might no longer be present.

In the light of obstructive emphy-

sema and atelectasis as a dominant factor in influenza the necessity for oxygen therapy becomes apparent. The use of expectorants and fluidifiers of the sputum should perhaps be studied again. The question of whether to increase the cough reflex or decrease it with sedatives should be reconsidered. Other problems for study may present themselves.

A child was recently brought into the emergency service of Harlem Hospital obviously suffering from an acute respiratory infection. The admitting physician made a diagnosis of acute bronchitis and since the child did not look seriously ill he sent it home. In eight hours it was dead. This is a classic picture that Cassasa has been meeting in his work as a medical examiner for the city of New York. We believe that these patients die from bronchial asphyxiation.

The conclusion can be drawn that any condition causing excessive accumulations in the bronchial tree, whether this is produced by allergy, infection, irritating vapors or various causes of pulmonary edema, is ideal for obstructive emphysema and atelectasis. This may be of such rapid occurrence that death takes place

before those who are in attendance can realize what is happening. Influenza is especially prone to produce such a picture.

941 Park Avenue

ABSTRACT OF DISCUSSION

DR. E. G. GALBRAITH, Toledo, Ohio: Atelectasis was produced by plugging the bronchus with a plug made from a rubber bath sponge. This work was done on dogs and then the dogs were killed at intervals ranging from thirty minutes to thirteen days after the obstruction was produced. In killing the dogs we injected iodized oil into the external jugular vein, which was immediately carried to the pulmonary artery, in an effort to demonstrate the presence of a filling defect in the vessels. This demonstrated rather clearly the steps that follow in the production of atelectasis. The first thing noted in the cases in which the obstruction had been present thirty minutes was a congestion of the blood vessels in the alveolar walls long before the alveolar walls were collapsed. This process gradually progressed until finally the air was absorbed and the typical pathologic picture of atelectasis resulted. From that point on, it was a question of atelectasis plus infection which always followed. The infection started in the bronchus and spread to the parenchyma and soon resulted in a definite pneumonitis, which if allowed to go on long enough, resulted in multiple abscesses and necrosis. In the early cases of atelectasis, no demonstrable defect in the filling of the pulmonary artery could be demonstrated, but within twelve hours it could be noted that the terminal arterial branches did not fill. This was interpreted to mean that they were already filled with blood and for that reason the iodized oil could not enter the terminal branches. It was concluded that the real mechanism in the development of atelectasis was a result of the lack of motion which takes place during the inflation and deflation of the lung and that atelectasis follows in this condition regardless of what produces it. Of course, in bronchial obstruction there is no inflation and hence no deflation to move the column of blood along, in other words, to empty the pulmonary veins. I feel that if for any other reason the lung fails to inflate and deflate, the same picture results. The chests of these dogs were roentgenographed and frequently in the early cases atelectasis did not show on the x-ray plate with the technique used. It was only after infection was superimposed that the atelectasis showed up well on the x-ray plate. I feel as Dr. Snow does that, if the conclusions I have drawn are correct the treatment is inflation. If there is obstruction present in the bronchus, that must be removed before the lung can be properly inflated.

DR. LE ROY SANTE, St. Louis: There is no doubt in my mind that atelectasis and obstructive emphysema play a greater part in the course of various diseases of the lung than we really give it credit for. I am sure that the autopsy and the pathologic material in various diseases bear this out many of the roentgenographic manifestations of tuberculosis, for instance, are undoubtedly due to associated atelectasis. Again, I am sure that I have made similar observations in infants to that referred to by the authors, that is, that infants constantly lying on their backs accumulate bronchial secretion posteriorly resulting in atelectasis of the lung with the accompanying compensatory emphysema of the anterior portion. Pediatricians have referred to this many times, stating that the conditions which they observed after they disturbed the child and brought him to the x-ray department for examination were entirely different from the ones they had obtained while the child was in bed. In a few instances they have actually been able to demonstrate on a film the obstructive emphysema and atelectasis that have occurred. There is however one conclusion that I have in mind as an exception to, and that is the statement that obstructive emphysema and atelectasis occur as a result of influenza. If the authors had said in children in place of influenza I would be willing to accept it but when they say in influenza I think that it at least conveys the impression that these changes occur as an ordinary grip as a direct result of the influenzal involvement. I think that perhaps the greatest factor is the debility of an infant rather than that it occurs as an actual accompaniment

⁹ Wessler, H. and Jach⁹ Leopold. *Clinical Roentgenology*, of Diseases of the Chest. Troy, N. Y. Southworth Company, 1923, p. 223.

of influenza. The authors have referred to emphysema and spoke of various different types of emphysema. If one is going to speak about the development of these changes and try to give x-ray evidence of their presence it is necessary to define one's terms. For instance, when one speaks of it as occurring in influenza one has to define what one means by influenza whether the ordinary common type of grip that is prevalent all the time or epidemic influenza of 1918-1919 and 1920 to which the authors have referred in which the main pathologic changes were due to the activities of other associated invading organisms. Waters showed some years ago that the x-ray appearances in ordinary grip consisted merely of an increase in the root shadows and the lung markings of both lungs.

DR ROBERT G. TORREY, Philadelphia. In 1918 Grosh of Toledo and I observed a large number of cases of influenzal pneumonia at Camp Hancock, Georgia, with 150 careful autopsy studies, and briefly we came to the following conclusions: Influenza is a disease of which the primary expression is an invasion of the lung alveolus with a weakening of its structure. Uncomplicated by other infections, it is a relatively mild disease. Complicated as it was in different camps and different cities by various other epidemic infections, as the hemolytic streptococcus, *Staphylococcus aureus* the Pfeiffer organism and the pneumococcus the disease gave different clinical and different roentgenologic pictures. We made a report entitled

Acute Pulmonary Emphysema Observed During the Epidemic of Influenzal Pneumonia, calling attention to these points: Epidemic influenza weakens the lung structure. If there is much coughing and strain, acute emphysema results. This may be only vesicular, or it may be also interstitial resulting in mediastinal and subcutaneous emphysema. If one lobe is over-distended another lobe must be relatively collapsed. This makes a confusing picture. The hemolytic streptococcus produces an intense bronchitis and peribronchitis. These dense infiltrates may give an x-ray picture indistinguishable from tuberculosis. The bronchial and pulmonary changes in influenzal streptococcal pneumonia are destructive not exudative, and repair is accomplished by fibrosis. The x-ray picture in the convalescent is distinctive. Mediastinal emphysema in the acute stage may show a spreading and convexity of the root shadows that are characteristic. The acute emphysema determines to a considerable extent the type of emphysema complicating recovery. These collections are apt to be located interlobar or in vertical columns forced into these locations by the over-distention of the lungs. A lobe which is over-distended or collapsed may be fixed in that state by a complicating lobar pneumonia.

DR WILLIAM SNOW, New York. I must again emphasize that we feel that emphysema in influenza is obstructive. I believe that the slides of roentgenograms that I showed brought out the point. There were seen displacements involving the mediastinum, the diaphragm and the interlobar fissures. In some instances I think one could see the widening of the intercostal spaces. Now in our opinion compensatory emphysema will not cause displacements. Obstructive emphysema implies increased tension distal to the obstruction and this can produce the picture we have presented and described. Though there may be a little difference of opinion we feel that atelectasis and emphysema in acute respiratory disease should be considered as an obstructive condition so far as it puts the lung out of condition. This approach is advantageous because it gives a method of attack which should be of real value to the clinician, the roentgenologist and the pathologist.

Dementia Praecox and Habits of Adjustment—In 1896 Moyer at the Worcester Hospital first started to develop his conception of dementia praecox as depending on a special constitution and personality likely to break down in specific manners. He stated the general principle is that many individuals cannot afford to count on unlimited elasticity in the habitual use of certain habits of adjustment and that the type of adolescent deterioration can very largely be traced to disharmonies of thoughts or habits and of interests which bring about a stunting in one direction or another.—*Miles Pompei*. *Dementia Praecox*. *Preventable Psychiatric Quart* 11:552 (Oct.) 1937.

PTOSIS AND ITS SURGICAL CORRECTION

EDMUND B. SPAETH, M.D.

PHILADELPHIA

Blepharoptosis, commonly spoken of ophthalmologically as ptosis, is the inability to raise the upper lid owing to paralysis or paresis of the levator palpebrae superioris muscle. Some congenital cases, especially those which are accompanied by a paralysis of the superior rectus have an anatomic defect present which is not purely innervational or paretic.

Ptosis may be congenital, may follow trauma, may continue as a part of the residuals of an inflammatory condition of the orbit or may be a part of a complete or incomplete external ophthalmoplegia, either central or peripheral in origin. Surgical ptosis should be considered as any one of these cases which is stationary, which cannot be corrected by any medical treatment and which impairs vision. Such a degree simply means that the weakened muscle is unable to raise the lid.

Fig. 2—Surgical technic necessary for the correction of a condition such as shown in figure 1.

against the resistance of the orbicularis palpebrae muscle plus the weight of the lid itself. Cicatrices in the upper lid and at the canthi may simulate a ptosis but, as long as the levator palpebrae superioris is not itself paralyzed, the correction of these cicatricial forms of ptosis is a simple matter of scar resection and of suture sufficient to permit the levator to function again as it should (figs. 1 and 2).

This paper has as its single reason the plea for diversified surgery in the correction of this condition. Terson has been aptly quoted as saying that "it is only with precise appreciation of the peculiarities of the individual case that one may hope to succeed in this delicate and special surgery of the lid." A correct diagnosis as to the character of the ptosis and an exact estimate of its degree are prerequisites to a satisfactory outcome.

For the moment three muscles of importance must be considered for the basis of all surgery for ptosis.

From the Peter Clinic, Graduate Hospital, University of Pennsylvania Graduate School of Medicine. Read before the Section on Ophthalmology at the Eighty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

Owing to lack of space this article has been abbreviated in *THE JOURNAL* by the omission of several illustrations. The complete article appears in the author's reprint.

exists in the utilization of one or more of these. The peculiar and important fact is that each muscle, when used, gives a maximum correction only under certain definite circumstances, or, reversing this statement, certain circumstances when present indicate definitely the necessity for utilizing one of these, if not exclu-

into the orbicularis oculi and the skin of the upper lid, the second into the upper border of the superior tarsal plate, the third into the conjunctiva and the fourth into the upper border of the margin of the orbital opening, that is, fusing with the septum orbitale in this manner (figs 3, 4, 5, 6, 7 and 8).

The superior rectus is histologically and embryologically in very close association with the levator and one can see how either could be utilized to replace the other (figs 9, 10 and 11).

The third, that is, the occipitofrontalis, is truly an accessory muscle of lid elevation in the course of its fibers and in its normal function. Each muscle can be subdivided into two portions—an occipital and a frontal. The frontal, which is the part of interest to ophthalmologists, is quadrilateral arising from the epicranial

Fig 3—Blaskovics technic for resection and advancement of the levator

sively at least to a major degree. The muscles are the levator palpebrae superioris, the occipitofrontalis, with the corrugator supercilii, and the superior rectus.

The peripheral distribution of the levator is of special interest through its fascial sheath, in common with the superior rectus, and the manner in which the belly of

Fig 5—Blaskovics technic for resection and advancement of the levator

aponeurosis and by this insertion into the skin at the eyebrow, interdigitates very closely with the fibers of the orbicularis and with those of the corrugator supercilii (figs 12, 13, 14 and 15).

Ptosis must be divided into two types of cases, those with and those without the surgical relationship which are being considered. Certain cases lie in a borderland between surgical and nonsurgical indications. For instance, one would not consider the correction of ptosis resulting from an intracranial neoplasm until the condition is in a state of a more or less permanent cure. A similar case is one of complete external ophthalmoplegia, either unilateral or bilateral (fig 16). In such instances diplopia would result and the cornea would probably be lost from consequent exposure and from drying. As far as contraindications are concerned the ptosis of myasthenia gravis is probably the best example of an absolute contraindication to surgery. In this condition the degree of ptosis is always changing. Intervals are present when there is no ptosis, and at other times the ptosis may be practically complete. The most classic of cases presenting a pure surgical relationship is that of congenital ptosis with an isolated paralysis of the levator palpebrae superioris.

Fig 4—Blaskovics technic for resection and advancement of the levator

the levator splits off from the superior rectus. This illustrates the reason for poor levator action in congenital ptosis when combined with poor superior rectus action. The common nerve supply to them is equally relevant. The fibers spread out in a fanlike aponeurosis and are inserted in a fourfold manner—one portion

Four general procedures are available. In spite of this the greatest good will be obtained from those surgical measures which do not rely for their success on a simple feature or principle but usually on a well considered union of two or more possibilities. In this manner one is not obliged to exaggerate a particular step and to risk, for example, the production of unsightly lagophthalmos, but one is able instead to obtain a maximum effect with a minimum disturbance of any one of the parts involved. The possibilities are shortening of the eyelid itself, advancement or advancement with resection of the levator, replacement of the levator by the occipitofrontalis, and last, the utilization of the superior rectus.

Fig 7—Technique of the Everbush resection and advancement of the levator

The first of these is usually quite unsatisfactory. Some correction is obtained from a tarsectomy but only in very moderate degrees of spacial ptosis cases. In the final analysis this amounts to a levator advancement (figs 17 and 18). Simple skin resections are futile for, if sufficient skin is excised to correct the ptosis, lagophthalmos and ectropion will develop. With the three remaining procedures to be considered each type of operation is best applicable to certain definite cases and not one of the three lends itself to all the cases that appear for correction. Furthermore, unilateral ptosis must be handled quite differently from bilateral ptosis. The ptosis of infants whether bilateral or unilateral must be treated quite differently from that of adults or even of older children. Patients with ptosis having some levator action still present should be operated on by some method which utilizes this to its fullest extent.

The operative procedures that have been presented are innumerable. Some of them are delightfully simple and usually of no great value. Others are rather complicated and do not offer unusually good results to compensate for the difficulties present in the technique outlined.

Fig 9—Original Motais technique

The ptosis of infants must be corrected, especially if bilateral, as soon as the infant begins to walk. The child will soon learn to throw back his head and develop thereby a faulty posture and a spinal curvature which

Fig 10—Kirby's and Shoemaker's modification

is quite distressing to see owing to the hyperextension of the head neck and spine. Crutch glasses may be used here as a stop-gap. I have done this with full satisfaction thus being able to postpone the ptosis operation until the fourth or fifth year of the infant's life. Unilateral ptosis cannot be operated by the utili-

zation of the superior rectus muscle. While the Motaïs-Parmaud procedures are based on sound physiologic and scientific bases, if the operation is successful for the correction of the ptosis a unilateral hypophoria is almost certain to develop. Too often the absence of such a hypophoria means, as well, an unsuccessful ptosis

Fig. 12—Technic of the Hess operation

operation. There are other factors to be considered in connection with the Motaïs operation. Success in its application depends on the normal integrity of the superior rectus. A large number of cases of congenital ptosis are accompanied by an insufficiency of this muscle. Hence a careful study of the upward ocular rotations must be made before the operation. The original Motaïs procedure calls for the dissection of a central tongue of muscle tissue from the superior rectus, this to be transplanted into the upper lid for a twofold purpose: (1) to hold the upper lid up and (2) to permit further elevation of the upper lid as the eyeball is rotated upward. It is absurd for one to think that this tarsus-superior rectus adhesion functions as

Fig. 14—Technic of the Hunt-Tansley operation for ptosis

a strip of muscle. As Shoemaker said, "It can act only as a cicatricial adhesion of the tarsus to the superior rectus." If this is believed, the rationale for some of the more recent modifications of the ptosis operation, such as Shoemaker's and Kirby's is logical. The deepening of the orbitopalpebral fold that occurs with the Motaïs operation is quite satisfactory. The eye is

rather prone to remain open during sleep, however, following a Motaïs operation more so with this than with any other of the operations. The reason is plain for the upward rotation of the eyeball, physiologically present in sleep, must also elevate the adherent lid. Winking, furthermore, may be rather difficult following this operation, for the eyeball normally remains fixed during the process. The attachment of the upper lid to the superior rectus now limits this in that the movement of the upper lid is quite dependent on the movement of the superior rectus.

Surgery that utilizes the occipitofrontalis has no effect on the levator palpebrae superioris. As Beard¹ states, "the frontalis owes its power of lifting the eyebrow to the fact that its attachment is essential to the skin, hence, procedures that call for deep or extensive incisions and other traumatism in the superior orbital region must result in scars that inevitably limit the natural movement of the parts."

The utilization of the occipitofrontalis, when properly used and with the proper indications, is a very nice

Fig. 17—Wheeler's technique for a tarsus resection

procedure. For unilateral ptosis, however, it does result in a peculiar facial grimace not wholly beautiful to view. Furthermore, the occipitofrontalis is rather likely to contract bilaterally in the largest number of cases. Hence, with unilateral ptosis the palpebral fissure of the normal eye would be widened. Still this fault, while unfortunately present, does not contraindicate the utilization of the occipitofrontalis when proper indications are present.

Surgery applied to the levator is ideal. Two conditions, however, qualify the permissibility of surgery to the levator. The presence of cicatrices, cicatricial contractions, and stab wounds and lacerations which have already sectioned the levator contraindicate surgery. There should be some levator action present if ideal results are to be obtained. The futility of surgery on the levator as "an all around procedure" lies in the fact that in a great number of cases the muscle is either absolutely inert or so insignificant in its power that satisfactory correction may not occur. Lindner² in his discussion of the Blaskovics operation for ptosis tells

¹ Beard, C. H. *Ophthalmic Surgery*, ed. 2, Philadelphia: J. B. Lippincott & Co., 1914, p. 246.
² Lindner, K. *Klin. Monatsbl. f. Augenheilk.* 9: 1 (July) 1934.

that even in complete paralysis of the levator the shortening of this muscle, plus the tarsectomy, gives results which are adequate for the greatest number of cases

Procedures Indicated for Ptosis

	Condition Present	Unilateral	Bilateral
A	Infants up to the age of 3 years	Crutch glasses	Crutch glasses
B	Children 3 to 5 years of age	Huot Tansley procedure utilization of occipitofrontalis	1 Hunt Tansley procedure utilization of occipitofrontalis 2 Modification of Motais
C	Children 5 to 15 years of age	1 Blaskovics if levator action is present 2 Huot Tansley	1 Blaskovics 2 Modification of the Motais
D	Adults uncomplicated and with levator action present	Blaskovics or some modification of a levator advancement	1 Modification of Motais 2 Blaskovics or some modification of a levator advancement
E	Adults bilateral without levator action but with superior rectus intact		1 Modification of the Motais 2 Resection with advancement of the levator (see Lindner's statement)
F	Adults unilateral without superior rectus or levator action of any degree acquired paralysis	1 Use of fascial sling utilization of occipitofrontalis 2 Hess' direct anchorage to occipitofrontalis 3 Hunt Tansley	
G	Adults bilateral without superior rectus or levator action of any degree acquired paralysis		1 Resection with advancement of the levator (see Lindner's statement) 2 Use of fascial slings 3 Bilateral Hess
H	Trachomatous ptosis	1 Tarsus and culdesac resection with advancement of the levator	1 Tarsus and culdesac resection with advancement of the levator
I	Children with acquired paralysis and without uncorrected or accompanying external ophthalmoplegia correction depends on the degree of involvement	1 Utilization of sutures which form permanent cleidral tracts 2 Hunt Tansley operation 3 Hess' all occipitofrontalis action	1 Utilization of sutures which form permanent cleidral tracts 2 Hunt Tansley operation 3 Bilateral Hess
J	Adults with conditions as in I (correction depends on degree of involvement) (complete third nerve paralysis—see L)	1 Utilization of sutures which form permanent cleidral tracts 2 Utilization of fascial slings 3 Hess 4 Muscle surgery with the superior oblique	1 Utilization of sutures which form permanent cleidral tracts 2 Utilization of fascial slings 3 Bilateral Hess
K	Ptosis with incomplete external ophthalmoplegia	1 Utilization of sutures which form permanent cleidral tracts 2 Crutch glasses 3 If no operation	1 Utilization of sutures which form permanent cleidral tracts 2 Crutch glasses 3 Bilateral Hess operation
L	Ptosis with complete ophthalmoplegia	Crutch glasses	Crutch glasses
M	Cicatricial ptosis	1 Sear resection and suture 2 Lid shortening operation (Lid vertical operation)	
N	Ptosis following long standing enucleation	1 Blaskovics or some similar levator muscle procedure 2 Lid shortening operation (Lid vertical operation) also a levator procedure 3 Sear resection	
O	Ptosis with neurofibromatosis	1 Tumor resection 2 Hunt Tansley with resection of the redundant tissue 3 If no operation	

is a very fine procedure and, used as indicated, gives most satisfactory results

A summarization of the procedures indicated for ptosis would in general give a classification similar to that in the accompanying table

The utilization of one or more procedure in a single case is not at all uncommon. This is especially true when one considers the correction of the complicated forms of ptosis (figs 19 and 20). Cicatricial ptosis, ptosis following long-standing enucleations, trachomatous ptosis and ptosis with neurofibromatosis are illustrations of these. Frequently a ptosis remains following the reconstruction of a socket and following complete blepharoplasty. While these special conditions can be included in the four groups just mentioned, it is relevant to call the reader's attention to them as well.

The selection of the operation that is to be used for an individual case is perhaps the most important point

Fig. 20—Skin resection to illustrate the initial correction necessary for the correction of the ptosis of neurofibromatosis

in ptosis surgery. None of the procedures are difficult. If an improper or ill advised operation is used in a single case, the best of technique in the performance of this operation will not give as satisfactory results as the proper operation would give even if it were done with less surgical finesse.

CONCLUSION

This most pertinent statement is reiterated. The surgical treatment of ptosis must be as variable as are the causes of ptosis and the other many circumstances connected with it. No one technique can combat more than one set of conditions. Each of the three major procedures must be utilized as the occasion demands. This is a universal surgical principle regardless of whether the problem is ophthalmologic, abdominal or orthopedic in nature. Beard's statement, "all who have had much experience in this branch of ophthalmic surgery will agree that the results of ptosis operations taken all in all are far from brilliant" is unfortunately true. It need not continue as a fact however, if as much attention is paid to the diagnosis and the complicating circumstances of this condition as is paid to the various possible characteristics connected with glaucoma and cataract.

1930 Chestnut Street

Considering the classification herein in such instances this must necessarily be a combination of two of the basic principles mentioned: (1) a shortening of the lid itself and (2) surgery on the levator. In general however levator surgery either advancement or resection

ABSTRACT OF DISCUSSION

DR FERRIS SMITH, Grand Rapids, Mich. Dr Spaeth has made a plea for the desirability and necessity of diversified surgical technic in correcting ptosis. He has presented an exhaustive analysis of the anatomy, pathology and surgical procedure involved in such correction. His is the attitude of a practitioner with a sound background, good judgment, splendid technical ability and surgical imagination. He provides for all types of lesion, some of which will come rarely into the experience of the average specialist. The entire consideration presumes the availability of a method which permits the operator to control, with exactness, not only the mechanical features of the repair but also its subsequent course to an end result. Most of the procedures proposed do not permit of such control. The fact that fifty-seven different procedures have been described for correction of this lesion is sufficient proof that many of these result unsatisfactorily. The great majority of cases may be easily classified as to causative defect and an appropriate corrective procedure selected. The net of this consideration may be set up as follows: There are two objectives to obtain function and to produce a cosmetic result; the latter consequent on the former. Lesions resulting from trauma, in which both muscles are paralyzed require the careful study and skilful management indicated by Dr Spaeth, while those resulting from central nervous lesions may require similar consideration, or, more frequently, no consideration at all.

DR DANIEL B. KIRBY, New York. I examine the width of the palpebral fissure in the primary position and then compare it with the width when the eye is directed upward and again when the eyes are directed downward. I also take pictures of patients for photographic report in every case. I examine the length of the fissure, the horizontal and also the marginal length as applied to the lower lid. An ideal case is one which in the congenital form has a partial development of the function of the levator or, in the acquired case, a partial remnant of the function of the levator. In these cases the resection procedure as applied to the levator by the conjunctival route is indicated. In cases in which there is complete or almost complete paresis of the levator with a palpebral fissure which actually narrows when the patient looks up because the lower lid follows the globe in elevation and the upper lid does not, there is a definite indication for the employment of the Mota's principle of transplantation of the superior rectus. In cases in which there is complete paralysis of the levator and superior rectus and in addition paralysis of the inferior oblique the condition is called paralysis of elevation by Dr Wheeler. The eye is in a position of hypotropia and cannot be used even though the ptosis is corrected. It is necessary to lift both the globe and the eyelid using the procedure devised by Dr Wheeler of resection and advancement of the superior rectus and advancement of the inferior oblique over the orbital margin. This will tense the remnants of the muscles even though no muscular action is produced and will elevate the globe. Then the Mota's or Parinaud principle may be employed to elevate the lid. Traumatic and new growth cases require special consideration. This covers the field of ordinary ptosis surgery and leaves no need for the employment of the frontalis in any case. It is true that the average ptosis patient will hold back his head, arch his brows and wrinkle his forehead in the effort to get the curtain of the lid above his pupil. This is undesirable and gives the typical curious expression. After the use of the frontalis this expression is continued. The upper eyelid normally slides back over the convexity of the globe as does the top of a roller desk. Attachment to the frontalis lifts it in an unnatural, straight vertical manner.

DR EDMUND B. SPAETH, Philadelphia. The reason for this presentation and the scientific exhibit is a statement which was made in my presence at the Kansas City meeting last year. A certain man said he uses the Hess operation for everything and gets full satisfaction. It was to refute such an erroneous and mischievous statement that I prepared this paper and the exhibit. As to the sling operation that Dr Smith mentioned, I believe that Dr Derby was first to discuss the use of fascial slings long before Dr Blair continued it in his ingenious use of fascia for various facial defects. Dr Smith was unnecessarily polite in saying I had forgotten the Trainor operation. I have found that it produces adhesions in fact, a symblepharon

between the superior rectus and the upper lid. I have done this twice and had to cut these adhesions loose in both instances. I am grateful to Dr Kirby for calling my attention to the palpebral fissure. That is very interesting. It should eventually further classify various indications for some procedure or, at least, so far as limiting further the indications for the Hess procedure. The same thought applies to Young's operation, that a symblepharon-like limitation occurs here. The Mota's or a modification of it, gives a longer cicatricial attachment without the limiting adhesions.

ENDOCRINE THERAPY IN CHRONIC CYSTIC MASTITIS

DEAN LEWIS, MD
AND
C. F. GESCHICKTER, MD
BALTIMORE

The term chronic cystic mastitis, not accurate in the strict sense, is applied to a benign lesion of the breast which is thought by many to be precancerous in nature. It is neither inflammatory nor strictly neoplastic. Recent studies would seem to indicate that the change in the breast in this disease are associated with disturbances in some of the glands of internal secretion.

Chronic cystic mastitis in its later clinical stages may be divided into two types: cystic disease characterized by the development of a number of cysts of appreciable size and adenosis¹ characterized by proliferative changes resulting in the formation of many nodules in both breasts—so-called shotty breast. Study of a large series of cases reveals an indifferent stage of chronic cystic mastitis common to the early phase of both cystic disease and adenosis. This indifferent stage, often referred to clinically as painful breasts or mastodynia, is more commonly the forerunner of adenosis than of cyst formation. Difficulty in distinguishing between these three clinical varieties of the disease has interfered with the interpretation of the pathologic changes in the breast and their correlation with endocrine physiology.

PAINFUL BREASTS

A frequent precursor of the lesion that may develop into true cystic mastitis is the painful breast. This condition is characterized by cyclic pain, which reaches its maximum intensity before the menstrual period. In the early stages the painful and tender tissue is usually in the upper and outer quadrants and feels like a flat granular area of increased density. Menstruation is usually regular, the patient is in her thirties and either is childless or has not been pregnant for five or more years. In married women with this complaint there is a high percentage of sterility. Mammary pain and tenderness, which is at first slight and premenstrual, becomes more severe and finally lasts throughout the entire cycle. Fear of cancer is often aroused and an area of increased density may be palpated in the breast. These patients are usually not undernourished and are not of the nervous type. The granular or nodular area of increased density which at first varies at different periods of the menstrual cycle may persist. Spontaneous regression may occur, but often adenosis and less frequently cystic disease supervene after a period of months or years.

This work was aided by a grant from E. R. Squibb & Co. From the Surgical Clinic and the Department of Surgery, Johns Hopkins Medical School and Hospital.
1. Lewis, Dean and Geschickter, C. F. Ovarian Steroids and Their Relation to Chronic Cystic Mastitis. *Am. J. Surg.* 24: 249 (May) 1912.
2. Cheate, G. J. and Cutler, Max. Tumors of the Breast. Edward Arnold & Co. 1911.

This early stage of chronic cystic mastitis characterized by persistent painful breasts may be successfully treated by endocrine therapy (usually estrogen administered intramuscularly twice a week in doses of 10,000 international units over a period of several months). In this paper only those cases which had not responded to the use of various types of breast supports, to ointments or to endocrine substances used in improper doses are included. In all there were ten such cases of persistent painful breasts treated. The majority of these patients were treated during 1934 and 1935 and a period of several years has elapsed in which to observe the results of treatment. The data on these cases are summarized in table 1. Two typical cases in which estrogen therapy was given are reported.

CASE 1—D B, a white woman, aged 36, was married but had no children. Her menstrual periods were regular. She had had one miscarriage twelve years before. For three years there had been pain in the breast associated with menstruation which had gradually become worse and more prolonged. The patient was able to feel small masses and experienced tenderness in the outer and upper quadrants of both breasts. On examination

1935 she received 60,000 international units of estrogen. She continued to take estrogen by mouth on alternate months for a period of one year. Palpation of the breasts gave negative results after this treatment and pain and tenderness disappeared. She was well when examined in September 1937.

In case 3, pituitary lactogenic substance was given.

CASE 3—A S, a white woman, aged 36 married had three children the youngest being 2½ years old. The menstrual periods were regular but were preceded by pain in the right breast. The patient complained of pressure on the ribs and pain in the breast. Both breasts transilluminated clearly. Neither was shotty but both were rather full and soft and of a doughy consistency seven days after the last period. The thyroid had been enlarged for some years. The patient complained of pain in the right breast which passed from above downward and radiated into the right arm. She had lost about 5 pounds (2.3 Kg.), and an indurated granular area about 5 cm in diameter could be palpated where the pain was felt. In December 1934 and January 1935 the patient received 20,000 international units of estrogen. She still could feel the indurated mass in the right breast. She said that this was tender. Three hundred and sixty bird units of pituitary lactogenic substance was administered in April 1935. In December 1935 the

TABLE 1—Endocrine Therapy in Bilateral Persistently Painful Breasts

Patient	Age	Menses	Condition and Duration	Therapy*	Result
D B 1934 married 1 miscarriage	36	Regular	Pain eaking outer upper quadrant for 3 years	Fetrogen 100 000 international units in 6 months	Well Jan 1937
F S 1934 widow no pregnancies	28	Regular	Pain early shotty for 3 years	Estrogen 60 000 international units in 7 months estrogen by mouth 1 year	Well Feb 1937
I McC 1936 married 1 miscarriage	31	Regular	Caking outer upper quadrant pain for 4 years	Estrogen 110 000 international units in 6 months	Well May 1937
M F 1935 single no pregnancies	39	Intramenstrual bleeding	Pain early shotty eaking mid upper for 2 years	Estrogen 45 000 international units in 1 month	Well after 1 month of treatment Jan 1937
A S 1934 married 3 children	36	Regular	Pain lumpy one dense area thyroid enlarged for 1 year	Estrogen 20 000 international units in 1 month prolactin 360 bird units in 2 weeks	Well 1937
I S 1935 married no pregnancies	21	Intramenstrual bleeding	Pain and dense area in outer upper quadrant for 2 months	Prolactin 540 bird units in 2 weeks	Well 1937
I T 1935 married 1 child	26	Irregular	Pain eaking outer upper quadrant for 5 years	Prolactin 600 bird units in 3 weeks	Well Oct 1936
A B 1936 married no pregnancies	53	Artificial meno pause at 34	Pain and lumpy for 1 year	Estrogen 140 000 international units in 4 months	Well May 1937

T R 1937 married 1 ectopic 1 stillborn	36	Irregular	Pain and disappearing lump	Estrogen 70 000 international units in 2 months	Improved May 1937

* Injections of estrogen in international units given twice weekly

both breasts were enlarged beyond the normal. They transilluminated poorly. Both breasts had a definite edge and were shotty. There were granular, flat and lumpy areas but no definite nodules were present. The patient was examined by Dr Bloodgood in April 1933 and again in October 1934. During this period although the patient was assured that her condition was not serious the pain was unrelieved and the dense areas and shottiness persisted. Estrogen therapy was begun in October 1934, the patient receiving 20 000 international units in one month. In 1933 for the first six months she received 10 000 international units a month. At the end of this time the lumpiness and pain in the breasts disappeared and the patient has remained well. She was last seen in August 1937.

CASE 2—E S, a white woman, aged 28 a widow with no children had regular but painful menstrual periods. She complained of pain in both breasts of three years duration the pain being worse before and less after her periods. She was seen by Dr Bloodgood in August 1934. He found both breasts larger and more lumpy than normal. He characterized both as shotty with a definite edge but not of the advanced Schummelbusch type. Because support of the breasts did not relieve the pain or lumpiness she was referred here for endocrine therapy. At the beginning of treatment there was increased density and tenderness in the outer and upper quadrants particularly in the left breast. The remainder of both breasts had a granular feel were shotty and transilluminated poorly. Estrogen therapy was begun in September 1934 with doses of 5 000 and 10 000 international units which were gradually decreased. Between September 1934 and May

area mentioned had disappeared and the patient was well. She was still well when examined in December 1936 and last reported that she was well in March 1937.

The histologic appearance of the tissues removed from the upper and outer quadrants of painful breasts was frequently demonstrated by biopsy performed prior to the last decade. Under the microscope the characteristic picture is a cluster of terminal tubules surrounded by increased amounts of connective tissue without any lobular formation. The tubules surrounded by periductal connective tissue may contain secretion (fig 1).

ADENOSIS

The changes noted in painful breasts may be followed by the development of adenositis. This condition is characterized clinically by the presence of multiple indefinite nodules or small shotty masses in one or both breasts usually distributed about the periphery. The tender and dense areas in the outer upper quadrant found in painful breasts are present in early cases. In such early cases the breasts are usually of fair size with considerable parenchyma. The menstrual cycles continue to be regular.

In fully developed adenositis (figs 2 and 3) the stroma of the breast is increased in density and the

size of the breast is reduced. The breast has a saucer-like or liver-like edge. Pain, flat areas of increased density and indefinite nodules are present, but in addition discrete multiple tumors may be palpated, which histologically may prove to be small papillomas,

Fig. 1—Section of tissue removed from a dense area in the outer upper quadrant in a case of persistently painful breasts. The terminal tubules are atypical and show no lobular formation. They are widely separated by hyperplastic periductal connective tissue.

minute cysts or nonencapsulated adenomatous areas. A dark, bloody discharge from the nipple was observed in 7 per cent of our cases. The patients with typical adenosis are usually in their late thirties or early forties. Menstruation is apt to be painful or irregular, or the cycle is shortened to twenty-six days or less. Nonparous women predominate. Pregnancy or the

Fig. 2—This illustration and figure 3 portray the pathologic features of adenosis. Here is a gross specimen showing increased density of the fibrous stroma with minute cysts and small papillary masses.

menopause may cause these changes to disappear. In rare instances a benign papilloma or comedocarcinoma develops. Usually, however, the condition is self-limited and terminates with the formation of multiple small cysts. Spontaneous return of the breast to normal before the menopause is rare, occurring in less

than 5 per cent of our series. The patients are usually high strung, nervous and underweight. The thyroid gland is often palpable, and a definite adenoma is sometimes found.

Twelve patients with adenosis in various stages were treated by endocrine therapy. The data on these cases are summarized in table 2. The histories of several typical cases are given here. In general, the treatment of this form of chronic cystic mastitis with estrogen is highly successful. Pain is relieved and most of the nodules and areas of increased density disappear or are reduced in size. A tendency to recurrence from eighteen months to two years after treatment is often noted, but this can usually be controlled with single injections of 10,000 international units given each month in the premenstruum.

CASE 4—E. K., a white woman, aged 27, is married but has no children, although both she and her husband desire them. Her menstrual periods are regular. About four years before admission severe pain was felt in both breasts before her

Fig. 3—A section showing a small intracystic papilloma and irregular epithelial proliferation in the terminal tubules in a case of advanced adenosis.

periods. At first this soreness lasted for one week before her periods. It is now nearly continuous. Four months before admission a lump appeared in the right breast. The patient received sixteen injections of anterior pituitary like principle and small doses of estrogen (250 international units) elsewhere. The tumor was slightly smaller after treatment but the pain was not relieved and the patient was advised to have her breast removed.

When seen in January 1936, the right breast was larger than the left but the breasts were otherwise normal on inspection. The left breast had a definite edge on palpation and was diffusely soft or lumpy, particularly in the outer and upper quadrant. The right breast also had a definite edge but had a large flat dense area about 4 cm in diameter in the outer and upper quadrant. The region in which the former lump was felt, the inner lower quadrant, was now normal. The patient received 40,000 international units of estrogen in January 1936. Thereafter she received 10,000 international units once a month for six months. The breasts have remained free from tumors and free from pain since the second month of injection. She was seen in January 1937 and both breasts were normal. Aug. 20, 1937 the patient was three and a half months pregnant. The size of the breast had nearly doubled; they were of uniform density and were free of palpable nodules.

CASE 5—M H, a white woman aged 46 has one child, aged 23 years. The patient had masses excised from each breast in 1929 and 1932. In August 1934 she presented herself with a lump in the lower part of the left breast. She thought that a nodule in the right breast had appeared and spontaneously disappeared. The patient's menstrual periods were regular. She had had an asymmetrical enlargement of the thyroid. Her basal metabolic rate was $17+$. She had been worrying and lost weight.

On examination there were indications of recent loss of weight and there was diffuse enlargement of the right lobe of the thyroid. Both breasts transilluminated somewhat poorly. Both breasts were shotty in the upper and outer quadrant with scars to the outer side of each nipple. There was a dense mass 2 cm in diameter in the lower hemisphere of the breast. Microscopically the excised masses showed epithelial hyperplasia with irregular lobule formation (fig 4). The patient received 30 000 international units of estrogen and 1 440 bird units of pituitary lactogenic substance. Secretion was obtained for four days. The patient remained well for nineteen months, all lumps disappearing. After this time pain and shottiness began to return and she received 40 000 international units of

Fig 4—Section in a case of adenosis made from tissue removed before treatment with estrogen. The tissue is rich in epithelial elements.

estrogen in May 1936. In October 1936 there was a tendency for the left breast to be slightly granular but the right breast was entirely normal. The patient has gained from 6 to 8 pounds (27 to 36 Kg). The patient was well January 1937 on one injection of 10 000 international units of estrogen a month. She has continued well without further treatment to date (September 1937).

The mammary changes in adenosis are characterized by epithelial proliferation which results in small intracystic papillomas or nonencapsulated adenomatous areas. Fibrosis or the formation of small cysts may supervene. The essential dysfunction is apparently in the pituitary which results in irregularities in the secretion of the ovarian hormones. The object of the estrogen therapy in these cases is to suppress the pituitary activity and to carry pathologic changes of the breast forward to a state of involution or fibrosis (figs 4 and 5). With estrogen therapy such fibrotic changes may be accompanied by cyst formation, so that for a time a few lumps in the breast replace the more diffuse mammary changes. In such cases prolactin therapy may stimulate involution (figs 6 and 7).

CYSTIC DISEASE

Cystic disease is characterized by the development within the breast of one or more cysts of appreciable size. Several cysts may develop over a period of several years in the same patient but not infrequently

Fig 5—Section made in tissue removed at biopsy from a patient who received 500 000 international unit of amniotin (Squibb) over a period of ten months for the treatment of advanced adenosis. Epithelial proliferation has been replaced by a marked fibrosis and early cyst formation.

when the patient is first examined there is but one cyst. Cystic disease, like adenosis, occurs more frequently in women who have not borne children. It occurs

Fig 6—Section of biopsy in a case of adenosis before treatment with pituitary lactogenic substance.

later usually in the forties or near the menopause in women with a regular menstrual cycle who are apparently healthy in other respects. Premenstrual pain or indurated areas in the breast are unusual. Cysts make their appearance quickly. The known duration of the

tumor is given in days or weeks rather than in months or years, as in adenosis. The breasts affected are well developed and contain increased amounts of fatty or fibrous tissue. The cyst is round, smooth and freely movable. It transilluminates clearly, and on aspiration

in May and June 1935. She took some estrogen by mouth that summer. This treatment was repeated in July 1936 at which time she received 20,000 international units of estrogen. Following this the lumps in both breasts entirely disappeared. In January 1937 the left breast was normal on palpation. There was a new cyst about 2 cm in diameter in the outer and upper quadrant of the right breast, however, which has appeared within the last six weeks.

That proper endocrine therapy may prove effective in chronic cystic mastitis is substantiated by clinical observations in which the disease has disappeared during the course of normal pregnancy. Experimentally cysts of the breast do not develop in rats maintained on high doses of estrogen if pseudopregnancy is induced with repeated injections of gonadotropic principle from pregnancy urine, although cysts can be produced in rats given high doses of estrogen alone. The following case illustrates the relationship of chronic cystic mastitis to ovarian dysfunction and the regression of the disease during pregnancy.

CASE 7—A white woman aged 32, had two children, the youngest being 10 years of age. In April 1934 one ovary and two thirds of the opposite ovary were removed because of cysts.

Fig. 7—Second biopsy from case shown in figure 6 one month later following the injection of 2,600 bird units of prolactin (Squibb). The acini show secretory activity and dilatation.

a cloudy milklike fluid is obtained. When one or more cysts have appeared and spontaneously disappeared, a residual area of fibrosis may remain. Rarely, as described by Reclus, multiple cysts of appreciable size may be present at the same time in the two breasts. A form of cyst may develop in a preexisting fibroadenoma during lactation.

Ten cases of cystic disease treated by endocrine therapy are summarized in table 3. In general, lasting results are more difficult to achieve with endocrine therapy in this form of the disease and dosage must be more carefully adjusted to guard against overtreatment. Case 6 is illustrative.

CASE 6—E. S., a white woman, aged 48, married, has one child aged 19 years and has had one miscarriage. Her menstrual periods have always been regular but she is now approaching the menopause. She has had active pulmonary tuberculosis for ten years and trouble with her breasts for four years.

Fig. 8—This illustration and figure 9 portray the pathologic features of cystic disease. Here is a gross specimen of a typical blue dome cyst.

A cyst was removed from each breast, one in August 1931 and another in October 1934. In April 1935 another lump appeared in the left breast. The breasts were well developed with scars in the upper hemisphere of both breasts at the

site of the previous operations. A lump 4 cm in diameter which feels like a cyst is felt in the outer and upper quadrant of the left breast and a like tumor in the upper inner quadrant of the right breast. The patient was given injections of estrogen as follows: She received 80,000 international units of estrogen

Fig. 9—Section showing fibrosis in a wall of a blue dome cyst.

and the patient was told that no further pregnancies were probable. Following the operation, pain more pronounced in the premenstruum developed in both breasts. The patient was first seen in November 1935. At this time nothing abnormal was palpated in either breast, but the pain had become continuous and there was mild galactorrhea. There was fear of cancer. The patient was given reassurance that her condition was not cancerous and told to return in six weeks. In January 1936, when the patient returned pain in both breasts had become constant. The menstrual periods had become irregular and the cycle was shortened to twenty-one or twenty-six days. At this examination indurated masses of breast tissue were palpated in the outer upper quadrants of both breasts. Definite masses were present in both breasts about 1 cm in diameter, one in the midupper hemisphere of the left breast and one in the outer upper quadrant of the left breast. The breasts at the periphery were soft and had a definite edge. No endocrine material was given but the patient was told to return for treatment. She did not come back, however, for over a year.

The patient was next seen April 3, 1937. She was ten months pregnant. The pain in the breasts was now intermittent but sharper and more stabbing since pregnancy. On examination a definite edge could still be felt in the left breast and the nodule persisted in the left breast but not in the right. In the right breast an indefinite dense mass was

palpated in the outer upper quadrant, there were no lumps and no definite edge. No treatment was prescribed. The patient was told to return in three weeks.

The patient was seen April 23, 1937. She was now five months pregnant. Pain had disappeared, the breasts were enlarged and no masses could be felt in either breast. She is breast or may be superimposed on early or advanced adenosis. In such conditions estrogen tends to inhibit the secretory activity and may complete the process of fibrosis. If the estrogen therapy is stopped suddenly or continued over too long a period, or given in doses

Injections of estrogen given twice weekly

being followed monthly until the end of pregnancy, and the breasts have continued to be free from pain and lumps.

In cystic disease the pathologic changes are characterized by increased amounts of connective tissue, by epithelial involution and hypermaturation and by secretory activity in the surviving living cells of the terminal tubules (fig 8). This secretory stage with cyst formation may occur in the abnormal involuting

of over 20 000 international units weekly, cysts may reappear. For this reason estrogen therapy in solitary cystic disease does not yield the same satisfactory results observed in painful breasts and in cases of adenosis.

In recent cases other endocrine substances—testosterone and progesterone—have been tried but without encouraging results.

COMMENT

The treatment of adenosis or of cystic disease by excision of the nodule-containing tissue is unsatisfactory, since the condition is chronic and nearly always bilateral, and similar tumors tend to appear in the same or in the opposite breast following excision. However, such local excision should always be performed in order to permit microscopic study if the clinician is unable to rule out carcinoma. If the pain-

* With few exceptions the operations performed in these cases were simple excisions.

ful nodular tissue is allowed to persist without further treatment after its benign nature is clinically established the patient often continues to be apprehensive of cancer despite reassurance by the physician. As the result of changing physicians, multiple excision and amputation of one or more breasts is the rule in at least one third of such cases. We believe that the performance of single or bilateral mastectomies is not indicated.

A review of the data on file in the Surgical Pathological Laboratory has convinced us of the benign nature of these conditions and the absence of a relationship to cancer. Of the 1,048 cases of adenosis and cystic disease shown in table 4, 523 have been followed for more than five years, and in this series carcinoma of the breast developed in only four patients (less than 1 per cent of the cases followed for more than five years).

In carrying out the endocrine treatment in these cases, it must be borne in mind that in general the various forms of chronic cystic mastitis are self limited and tend ultimately to regress. The hormone therapy is a convenient form of palliative treatment preventing needlessly mutilating operations and, if it is properly used, in our opinion it speeds the regression of the disease. Favorable results with this form of treatment have been reported by Mazei⁴ and by Dahl-Iversen.⁵ The results are most satisfactory in persistent painful breasts and in early adenosis.

Successful endocrine therapy in chronic mastitis requires relatively high doses of estrogen. Ten thousand international units is injected intramuscularly twice weekly for a period of three weeks (between two menstrual periods), a total of approximately 60,000 international units being given. This is followed by similar doses injected once a week for another month, then twice the following month. After this a single injection is given in the premenstruum or capsules are taken by mouth every other day to complete six months of treatment. The oral preparation used is amniotin (Squibb) in capsules containing 2,000 international units of estrogen each. The estrogen is never given during menstruation and treatment is usually continued for a period of six months.

In some cases in this series estrogen plus pituitary lactogenic substance was tried instead of estrogen

alone. Thirty thousand international units of estrogen was given the week before menstruation. Following menstruation pituitary lactogenic substance therapy was begun. This substance should be administered daily or twice daily for a period of one or two weeks until secretion is obtained. The total dose required is in the neighborhood of 1,000 bird units. The material is administered intramuscularly in aqueous solution and usually 1.5 cc (containing 40 bird units per cubic centimeter) is given as a single dose.

Lacassagne induced carcinoma of the breast in mice with injections of estrogen in strains to which the females were normally susceptible. Because of these experiments, estrogen therapy is looked on by some as increasing the possibilities of the development of carcinoma of the breast in patients. Such an interpretation of these experiments seems illogical, since it fails to evaluate the factor of dosage. In Lacassagne's experiments estrogen in excess of one millionth of the body weight of the mouse was administered at a single dose, and the dose was repeated weekly throughout the life of the animal. A corresponding dosage in a patient weighing 50 Kg would necessitate the administration of 50 mg of crystalline estrogen at a single dose and the injections would have to be begun in early childhood and continued throughout life. The estrogen therapy used in chronic cystic mastitis is well below the amounts present in normal pregnancy. The safety factor in this form of therapy is therefore well within all reasonable limits.

THE LENGTH OF THE INGUINAL LIGAMENT

IN THE DIFFERENTIATION BETWEEN DIRECT AND INDIRECT INGUINAL HERNIA

FRANKLIN I. HARRIS, MD

AND

ALFRED S. WHITE, MD

SAN FRANCISCO

A review of the development of the surgical treatment of hernia shows that the interest in this subject has been focused largely on the technic of operative repair and that only cursory attention has been given to the preoperative diagnosis of the types of inguinal hernia. The explanation for this is apparent in that the surgeon depends ultimately on his actual observations at operation for the determination of the surgical procedure that he will use. In other words, the differentiation between direct and indirect types of hernia has not been of particular preoperative importance. The determination of the presence of a hernia has been sufficient.

During the past few years, while engaged in the study of the injection method in a series of 300 cases,¹ we have felt the need for such a presurgical differential diagnosis and have developed certain diagnostic points which heretofore have not been described or, if described, have not been emphasized in connection with the differential diagnosis of inguinal hernia. These diagnostic features appear to be of great practical value not only to surgeons interested in the injection therapy

but also to those interested in recurrences following the surgical treatment

Measurements of the inguinal ligament have been made in 500 patients. All patients were males, over 20 years of age, with normal pelvis. The distance measured was that between the anterior superior iliac spine and the spine of the pubis. A remarkable variation in the length of the ligament was noted. Measurements were obtained that varied between 9 cm and 19 cm. It was apparent that a variation of 10 cm must have

the intraspinal distance did not increase in proportion to the increase in the length of the inguinal ligament. The longer the inguinal ligament, the shorter was the relative distance between the spines. In such cases the pelvis is of greater depth. Conversely, the shorter the ligament, the more shallow the pelvis (table 2).

In indirect hernias, then, the pelvic floor is relatively flat and the intra-abdominal pressure is exerted more evenly over the entire inguinal ligament. In direct hernias the pelvic floor is relatively markedly inclined and the intra-abdominal pressure is exerted more particularly near the midline, as shown in the illustrations. This seems logically to explain the formation of direct inguinal hernia in patients with long inguinal ligaments. With a more even distribution of pressure, as in patients with short ligaments, a congenital weakness at the internal ring is necessary for the formation of an indirect hernia.

While an analysis of the measurements of the length of the inguinal ligament is important as an aid in the differential diagnosis of inguinal hernia and is especially important for the injection treatment, there is still another consideration of major interest. This concerns an analysis of those cases which have recurred after surgical treatment. As will be noted in table 1, there have been fifty-eight cases of inguinal hernia that have recurred following surgical repair. The average length of the inguinal ligament in these cases has been 15.5 cm, considerably higher than the average for the pure indirect type.

The prognostic significance of these observations when the operative repair of an inguinal hernia has been performed is of interest. It was found that practically all the recurrent postoperative indirect hernias examined had inguinal ligaments which approached the so-called maximum length of 15 cm for the pure indirect variety. It may be presumed therefore that an operative repair in the case of an indirect inguinal hernia with a relatively short inguinal ligament has a much greater chance for a permanent cure. Those presenting a long inguinal ligament must be particularly watched for a tendency toward recurrence. It is probable that the recurrences noted in these cases were

some significance in relation to the mechanics of the formation of inguinal hernia. Of the 500 cases in which measurements were taken, 300 patients had inguinal hernias. An analysis of the types of hernia in these cases revealed forty-six cases of direct hernia, 207 cases of indirect hernia and forty-seven cases in which both a direct and an indirect element were present. A comparison of the type of hernia present and the length of the ligament revealed an extremely important point. In cases diagnosed as indirect hernia the measurement of the inguinal ligament was always less than 15 cm. In cases diagnosed as direct hernia the measurement of the inguinal ligament was always greater than 15 cm. Measurements of the forty-seven patients diagnosed as having both a direct and an indirect element to their hernias likewise uniformly showed distances of less than 15 cm. The results of these observations are shown in table 1.

As our experience has increased and as a greater number of cases have been examined, a comparison of the types of hernia with the lengths of the inguinal ligament has shown that a definite relationship exists between them. It appears that in individuals with inguinal ligaments of less than 11 cm there is little tendency for the formation of inguinal hernia. In those individuals whose inguinal ligament measures between 11 and 15 cm the appearance of a hernia is always through the internal ring and is of the true indirect inguinal type. As the inguinal ligament approaches the maximum length of 15 cm for the indirect type there is found a greater tendency toward the occurrence of the mixed type of hernia, that is, the combination of a well developed indirect hernia and a partially developed direct element. Cases of hernia appearing in individuals with ligaments measuring from 15 to 19 cm were always of the pure direct type, that is, through Hesselbach's triangle.

In addition to the measurement of the length of the inguinal ligament measurements were taken of the distance between the two anterior superior iliac spines. It was found that the distance between the spines increased with the length of the ligament. However,

TABLE 2—Analysis of Relationship of the Length of the Inguinal Ligament to the Distance Between the Anterior Superior Iliac Spines

Length of Inguinal Ligament	Average Distance Between the Spines
10 cm	22.5 cm
11 cm	23.5 cm
12 cm	23.5 cm
13 cm	23.5 cm
14 cm	24.0 cm
15 cm	24.0 cm
16 cm	27.0 cm
17 cm	28.0 cm

present as a potential direct hernia at the time of the original operation for the repair of the indirect element. As our observations indicate, a tendency toward the mixed type of hernia is present in patients with this length of inguinal ligament.

This seems to indicate that here, then, is a means of segregating those cases which are most apt to recur after surgical repair. Special care in operative technique, with particular attention being given to the closure of Hesselbach's triangle, and more careful postoperative treatment may then be given to patients in this group. A closer follow up with the purpose of finding early recurrences and instituting the injection method may be considered.

Measurements of the length of the penis were also taken and compared with the measurements of the inguinal ligament. The distance measured was from the dorsal root of the penis to the tip of the glans. Generally speaking, it was noted that the length of the penis varied inversely with the length of the inguinal

between direct and indirect hernias and those hernias which present a combination of the two types cannot be overemphasized, for on this differentiation depends the success or failure of the injection method. Such a differentiation between the various types of hernia must be made before the beginning of therapy when the

Fig. 1—Schematic drawings from actual patients with the lengths of the inguinal ligaments and the distances between the anterior superior iliac spines accurately drawn to scale. *A* This patient had a direct hernia. Note the 19 cm inguinal ligament and the 28 cm distance between the spines. The penis measured 4 cm. Note the steep inclination of the pelvic floor. *B* This diagram also shows a patient with a direct hernia. Inguinal ligament measures 16.5 cm. Distance between the spines 26.5 cm. Note that with the shortening of the ligament the pelvic floor is relatively less steep. *C* This patient had a potential hernia with markedly dilated rings. Note the short inguinal ligament and the relative shallowness of the pelvic floor. Also note the increase in the length of the penis as the ligament becomes shorter.

ligament. In other words, the longer the ligament, the shorter the penis.

A comparison of these measurements with the type of hernia showed the same correlation as the length of the ligament. In patients with indirect inguinal hernia the measurement of the penis was practically

injection method is to be used. The correct placement of the truss and the proper placement of the injections depend on this exact differential diagnosis. Other diagnostic maneuvers for the differentiation of the direct and indirect types of hernia have been described elsewhere.²

Fig. 2—*A* This patient is normal. There is no evidence of hernia. The inguinal ligament measured 10.5 cm. Note the extreme shallowness of the pelvic floor. *B* This patient has a small indirect inguinal hernia. Note that while the pelvic floor is shallow it is somewhat less so than the normal shown in *A*. *C* This patient had an indirect inguinal hernia. Note that the length of the inguinal ligament is 14.5 cm and that the pelvic floor is much steeper. While to superficial examination patients *B* and *C* are identical as far as the presence and type of hernia is concerned, follow-up study shows that recurrences develop almost entirely in patients such as shown in *C*.

always more than 7 cm, whereas in those patients who had direct inguinal hernia the measurement was always less than 7 cm. While this observation has not been entirely consistent as the measurements of the ligament it is present often enough to be of definite aid in the differential diagnosis.

With the development of the injection method of treatment of inguinal hernia, the exact differentiation between the direct and the indirect varieties has become of urgent importance. The necessity of different

SUMMARY AND CONCLUSIONS

1. There is a definite relationship between the length of the inguinal ligament and the occurrence of either a direct or an indirect inguinal hernia.
2. Individuals with an inguinal ligament of less than 11 cm have slight tendency toward the formation of inguinal hernia.

² Harris F. I. and White A. S. The Truss in Pelvic Hernia. *Ann. Surg.* 64:443 (May) 1937.

3 Hernia occurring in individuals whose inguinal ligament measures from 11 to 15 cm are of the indirect type

4 Hernia occurring in individuals whose inguinal ligament measures from 15 to 19 cm are always of the direct type

5 Recurrences following surgical repair of inguinal hernia are more frequent in patients with long inguinal ligaments

6 The relative shortening of the distance between the anterior superior iliac spine explains the formation of direct hernia in patients with long inguinal ligaments and the formation of indirect hernia in patients with short inguinal ligaments

7 Additional diagnostic maneuvers in the differentiation between the various types of inguinal hernia are of importance to the success of the treatment of hernia by the method of injection

Clinical Notes, Suggestions and New Instruments

ACUTE INFECTIVE LARYNGOTRACHEOBRONCHITIS

ILLUSTRATING THE USE OF EPINEPHRINE (1:1000 SOLUTION)
INTRATRACHEALLY FOLLOWING TRACHEOTOMY

HERRMAN GREEN M.D. AND ERWIN P. MILLER M.D.
RIVERSIDE CALIF.

J. P., a girl, aged 17 months, was admitted to the Riverside Community Hospital, Jan. 5, 1937, because of an acute obstructive respiratory difficulty. The onset three days before was characterized by hoarseness and a high temperature (not recorded), followed by a croupy cough. On the second evening the rectal temperature rose to 104 F., with increasing laryngeal stridor and prostration. On the night of admission to the hospital the child seemed in such distress and so exhausted that intubation was attempted, but the tube was immediately expelled, bringing with it a plug of thick, gummy material. The child then breathed with greater ease for only a few hours, as obstructive symptoms returned with even greater intensity. Without further delay on the second hospital day a low tracheotomy was performed by one of us (E. P. M.), a No. 3 tube being inserted. Thick, gummy material plugged the tube, often necessitating the removal of both inner and outer tubes for cleaning. During the next three days death appeared certain a number of times when these viscid crusts seemed to form below the tube in the trachea and bronchi. This material was so tenacious that it could not be removed by catheter and suction. The child was saved from suffocation repeatedly by the instillation of epinephrine (1:1,000 solution), from 6 to 10 drops, through the tracheotomy tube. The shrinkage of the mucous membrane occasioned by the epinephrine caused these viscid plugs to be released and instantly expelled into the tube, from which they could be removed. On one occasion a plug was aspirated into a bronchus, and acute massive collapse of the left lung occurred. Complete expansion returned however, within four days. By the sixth postoperative day the tracheal secretion had become so thin that severe obstructive symptoms no longer occurred and the use of epinephrine was discontinued. Edema of the larynx persisted for two and one half weeks, necessitating the retention of the tracheotomy tube during that period. Following its removal convalescence was uneventful, and recovery seemed complete by the end of the fourth week.

During the acute illness the temperature ranged from 101 to 106 F. Auxiliary therapeutic measures included a blood transfusion, continuous intravenous drip (three days) and steam inhalations.

Culture from the tracheal secretion revealed *Streptococcus viridans* and *Micrococcus catarrhalis*.

COMMENT

This case is reported because we believe that, since bronchoscopic aspiration was not possible, the use of epinephrine solution by instillation, following tracheotomy, repeatedly relieved the obstruction during the period of great emergency.

PERFORATION OF THE GALLBLADDER OCCURRING IN THE LATE STAGE OF PREGNANCY

WADE W. STONE M.D. TOLEDO OHIO

In reviewing a series of gallbladder conditions I had occasion to reconsider a case of ruptured gallbladder complicating an eight months pregnancy. The rarity of this complication justifies a report for the medical literature. Rupture of the gallbladder is not an unusual condition, and every year it is reported with increased frequency. Alexander¹ reported twenty perforations in a series of 1000 cases, George² in 1925 reported 348 cases of perforation of the gallbladder, Heuer³ reported a 25 per cent incidence of perforations in a group of seventy-four cases, Judd and Phillips⁴ found sixty-four perforated gallbladders in a series of 508 cases of acute and subacute cholecystitis, Steinke⁵ reported a 15 per cent incidence of perforations in a group of 200 acutely inflamed gallbladders. The occurrence of a spontaneous rupture of the gallbladder as a complication in the late stages of pregnancy is extremely rare. A careful search of the literature fails to reveal a single case.

The following case is presented first, because of the absence in medical literature of perforation of the gallbladder complicating the late stages of pregnancy and second, because I feel that drainage of the abdomen effected by colpotomy as well as routine drainage of the upper part of the abdomen was the big factor in enabling the patient to survive what appeared to be an overwhelming peritonitis.

REPORT OF CASE

Mrs. M. L., aged 23, was seen in consultation with Dr. Horace K. Beckwith, Oct. 14, 1932, because of extreme distention and severe pain in the abdomen. The patient's family history was not particularly important. She was a primipara and had been married two years. She had had the usual childhood diseases without any complications. The menstrual periods began at 12 years, occurred every twenty-eight days and lasted from two to five days, the flow being considered normal in amount, and the patient suffered only occasional abdominal distress at this time. The last menstrual period occurred Feb. 11, 1932. Quickening was felt at four and a half months. Nausea and vomiting were present during the first three months of pregnancy, with occasional headaches. There was slight edema of the ankles at times. The patient had a very small amount of leukorrhea. She had had symptoms of frequency and burning on urination for some time previous to admittance to the hospital. The onset of her present illness occurred two days previously, with sudden sharp pain in the upper right quadrant, which radiated to the right shoulder blade. This was accompanied by nausea and vomiting of bile-like material. The pain was knife-like in character and had become generalized during the twelve hours previous to her admittance to the hospital. There was also gradual increasing distention of the abdomen, with marked shortness of breath.

When she was examined she was lying in bed, breathing rapidly and with great difficulty. The oral temperature was 99 F. and the respiration rate 50. There was a lemon tint to the skin which was generalized in its distribution, with rather marked flushing of the cheeks. There was marked sordes of the lips and a coated tongue, but the throat was normal. The scalp and cranium were normal. The pupils were round, equal and regular and reacted to light and in accommodation. The nose and ears were normal. The thyroid and cervical glands were not palpable. Respirations were very rapid—chal-

5 Steinke C. K. *Am J Surg* 27:132 (Jan.) 1935

low and labored, the breath sounds were harsh and the voice was normal with no rales, a percussion note was resonant throughout the entire chest. The breasts were pendulous and the nipples were erect and pigmented. The heart was normal in size with no murmur or thrill and a rate of 120, the blood pressure was 110 systolic, 78 diastolic. There was marked distention of the entire abdomen, with tenderness and muscle spasm, there seemed to be more tenderness in the upper quadrants than in the lower, the fundus of the uterus could be easily outlined two fingerbreadths above the umbilicus. Vaginal examination was not done. The extremities showed very slight edema about the ankles. The white blood cell count was 11,800. Urinalysis revealed a trace of albumin, one plus sugar, two plus acetone and a trace of diacetic acid, microscopic analysis of the centrifugated specimen revealed an occasional pus cell and an occasional red blood cell. Because of the sharp pain in the upper part of the abdomen, with the history of pain radiating to the right shoulder, the low fever, generalized distention with muscle spasm and the icterus of the skin, a diagnosis of acute cholecystitis with perforation complicating an eight months pregnancy was made. The patient was given 50 cc of 50 per cent dextrose intravenously and one hour later received 1,000 cc of saline solution under the skin. The pulse had increased 10 per minute and respiration was more labored than at the first examination. It was decided that it was imperative for the patient to have an abdominal section for peritonitis, and cesarean section to insure a live baby.

Five hours later the patient was taken to the operating room, where, under local anesthesia, a high median incision was made. When the peritoneum was opened an enormous amount of bile-stained fluid was encountered. The uterus was hastily opened through a high classic cesarean section, and an eight months baby was delivered. A hurried exploration of the upper part of the abdomen revealed a gallbladder containing three stones, the facet of one penetrating through the full thickness of the walls of the gallbladder. A small stab-wound drain was made in the right upper quadrant, the stones were removed and a tube was sutured into the gallbladder, a section of the gallbladder being sent to the laboratory for culture. A tube containing iodized gauze was placed in the lower angle of the main incision, which was hastily closed in layers. The patient was then prepared vaginally and posterior colpotomy was done, a tube being inserted and sutured to the cervix. The patient's condition at all times was very poor and she was given 2,000 cc of physiologic solution of sodium chloride intravenously during the operation. The patient was placed on the usual treatment for peritonitis. Her pulse two hours after the completion of the operation was in the neighborhood of 180 at the apex and the respiration rate was 50. A blood transfusion was given to the patient that evening.

The patient's temperature on the following day was 101 F, the pulse 130 and of better volume, while the respiration rate was down to 34. The cholecystostomy tube functioned well from the start. There was considerable drainage vaginally. Hot liquids in small amounts were started on the second day and the liquid diet was gradually increased. The patient passed a large amount of flatus on the morning of the third day and had two aqueous evacuations later that day. From this time on the peritonitis subsided rapidly. The patient's general condition improved steadily. The main incision was grossly infected, the patient having a temperature varying from normal to 100 F for a period of over a week. The cholecystostomy tube remained in place eleven days. The patient's temperature gradually subsided. The wound improved slowly with the aid of frequent irrigations with solution of potassium permanganate. The patient was not allowed out of bed until twenty-four days after the operation and was discharged on the twenty-fifth postoperative day. Urinalysis postoperatively revealed the presence of many pus cells with little or no albumin. Shortly after operation a few granular cast and red blood cells were noted, but these soon disappeared. The patient's convalescence was so uneventful as to make it unnecessary to report it in detail. The culture of the wall of the gallbladder revealed gram-negative bacilli, probably of the colon type group.

The patient was seen in her home by her family physician and was not seen again by me until a period of three weeks had elapsed. At that time there was slight drainage from the gallbladder incision, the main wound, however, was well healed. There was very little vaginal drainage. The baby was reported as doing very well. The patient was seen again on December 12. She had gained considerable weight. Both abdominal wounds showed a marked tendency to keloid formation. On vaginal examination the uterus was found to be small and in good position, no masses were felt on either side. Urinalysis was negative. The baby was reported to be steadily gaining in weight. About four years elapsed before the patient was again seen. She had gained tremendously in weight, having gained 85 pounds (38.6 Kg) since her discharge from the hospital. She stated that she had occasional burning in the epigastrium, particularly if she was not careful of her diet. She had some tendency to so called gas on the stomach and was occasionally nauseated but rarely vomited. The menstrual periods had become somewhat irregular and scanty. It was thought that because of the change in the menstrual cycle, with a tendency toward obesity, the patient was suffering from some glandular dyscrasia, partially at least of ovarian origin. There was a hernia in the lower angle of the cesarean incision. The cholecystostomy wound was well healed without any evidence of hernia. It was suggested to the patient that she be placed on a reduction diet and that the glandular deficiency be remedied. It was thought that at a later date it probably would be necessary to have cholecystectomy and a repair of the ventral hernia.

COMMENT

There might be reason for argument that the fetus should have been delivered vaginally and the peritonitis then treated by surgical drainage. I felt, however, that the chances for saving the patient as well as the baby were considerably greater by proceeding along the lines described here.

CONCLUSION

In a case of ruptured gallbladder complicating the late stages of pregnancy, prompt surgical intervention saved the lives of both the mother and the child.

421 Michigan Street

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

NEW CENTURY SUNLAMPS N-1 AND N-2 NOT ACCEPTABLE

Manufacturer: New Century Foods, Inc., Burbank, Calif.

It is one of the functions of the Council on Physical Therapy to report, from time to time, on devices recommended for use in physical therapy. Inquiries have been received recently with regard to the New Century Sunlamps N-1 and N-2. The evidence an interest in the advertising claims made for the lamp particularly concerning their ultraviolet radiation efficiency. Consequently, the Council has given consideration to the advertising copy circulated in connection with the New Century Sunlamps.

An advertising pamphlet, 'Light Your Way To Health' states that the two units are intended 'for either localized or general body treatments'. The N-1 unit according to the pamphlet, is a portable model hand lamp coming in a carrying case. The N-2 unit may be used on a chrome-plated stand.

From information given in the advertising the apparatus appears to utilize the mercury glow type of burner housed in a reflector. The Sunlamps cost less than any other old quartz lamp. It is stated that the average treatment time is four minutes but the distance at which the lamp is placed for this time interval is not mentioned. Both units

are equipped with automatic switches. They are said to consume 30 watts per hour. An ultraviolet lamp with this type of emission should be used only under the direction of a physician in the opinion of the Council.

The advertising matter, apparently written for public consumption ("Light Your Way to Health"), contains unsubstantiated physical claims concerning the effects of ultraviolet radiation which are misleading and inimical to the welfare of the public. For example, these statements are found in the copy "Ultraviolet rays increase body resistance to disease," "Ultraviolet rays soothe the nerve endings, thus relieving pain." Neither of these assertions is supported by critical evidence.

A form letter was also submitted to this office, evidently put out by the New Century Foods, Inc., apparently addressed to the potential purchaser. This contains many therapeutic claims that have not been supported by critical evidence such as the following: "that the tonic use of (ultraviolet) radiation for adults approaches more clearly to the effect of rejuvenation than any other generally practicable system. There is a great increase in vigour, alertness, and resistance to fatigue," "increases red cells and haemoglobin, the anti-infective quality of the blood", "The fagged-out business or professional man, the over-worked or over-playing society woman, the weak undeveloped child with no demonstrable pathology, these begin to flourish with ultraviolet light treatment. They no longer catch colds readily."

Furthermore, the aforementioned form letter includes reference to the influence of ultraviolet rays on specific conditions such as eczema, arthritis and catarrh. This sort of advertising leads to self diagnosis and home treatment. Unfortunately in many instances the underlying pathologic condition continues undiagnosed and untreated thus leading to serious consequences.

With regard to the ultraviolet emission, the form letter states that "the New Century Sunlamp supplies potent ultraviolet rays in much greater abundance than sunshine. It generates exactly the same quality ultraviolet rays as the most expensive medical lamps." So far as is known, the sun is the most abundant radiator of ultraviolet radiation.

In view of the foregoing facts, the Council on Physical Therapy voted the New Century Sunlamps N-1 and N-2 inadmissible for inclusion in its list of accepted devices, basing its decision on the unwarranted and misleading therapeutic claims made in the advertising.

ROSE CW-5 RADIATHERMY UNIT ACCEPTABLE

Manufacturer E J Rose Manufacturing Company Los Angeles

The Rose CW-5 Radiathermy Unit is intended for medical and surgical use. It is equipped with terminal outlets to permit the use of inductance cable, pad electrodes and electro-surgical accessories for cutting and coagulating. The unit is portable but can be used as a cabinet model. The weight is 66 pounds.

Rose CW-5 Radiathermy Unit

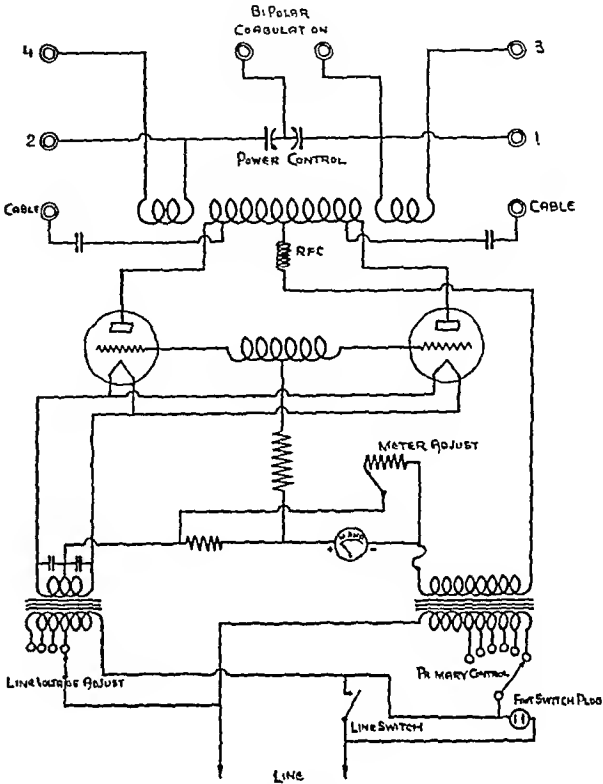

It is wired as a tuned plate, tuned grid, push pull oscillating circuit employing two tubes. The patient circuit is inductively coupled to the oscillator with a variable condenser incorporated in the circuit for tuning purposes. The wavelength is approximately 13 meters.

The input power required to operate it at full load for a period of two hours is 1300 watts. Since no acceptable means has been proposed for measuring the output, no claims are made. However, a phantom load test by means of electric light bulbs connected through condenser pick up plates and arranged to activate a photo-electric cell and calibrated meter approximates 480 watts.

The transformer temperature rise and the rise of the temperature within the cabinet taken at various levels are within the limits of safety prescribed by the Council. Burns may be

produced but can be avoided by the use of proper precaution. They are less likely to occur than with the conventional type of diathermy.

A series of tests were run by a reliable investigator and submitted by the firm as evidence of the effective heating properties of the unit. Eight tests were made with the inductance cable technic and eight cuff electrodes. Eight healthy

Schematic diagram of circuit

male medical students were used as subjects. Four were used for each method of application, each man submitting to two tests, one test on the right thigh and one on the left. Temperature measurements were made by the usual thermocouple method in the anterior portion of the thigh at depths of one-eighth inch, three-fourths inch and 2 inches or on the bone. These depths were measured from the skin straight in, that is,

Averages of Eight Observations, Coil Technic

Deep Muscle		Subcutaneous		Skin		Oral	
Initial	Final	Initial	Final	Initial	Final	Initial	Final
100.3	104.6	99.5	103.3	94.9	102.8	98.4	99.1

Averages of Eight Observations, Cuff Technic

Deep Muscle		Subcutaneous		Skin		Oral	
Initial	Final	Initial	Final	Initial	Final	Initial	Final
100.0	103.7	99.3	104.4	94.9	100.2	97.4	98.9

normal to the skin surface. Each of the measurements given in the tables represents an average for eight observations.

The unit was tried out in a clinic acceptable to the Council and found to give satisfactory service. It was found to perform as successfully as other units of the same general type.

In view of the foregoing favorable report on the unit, the Council on Physical Therapy voted to include the Rose CW-5 machine in its list of accepted devices.

Council on Pharmacy and Chemistry

The Council on Pharmacy and Chemistry of the American Medical Association records with deep sorrow the death of

GEORGE HENRY SIMMONS

George Henry Simmons was born in Moreton, England, Jan 2, 1852. He died in St Luke's Hospital, Chicago, Sept 1, 1937. Dr Simmons's life and death were in harmony with his wishes. He was spared lasting disease and suffering, retaining his mental faculties and his varied interests in human welfare to the end. He spent the years following retirement happily but not in idleness. Indeed, he continued to take a lively interest in those things to which he had devoted the greater part of his life—medicine and the welfare and happiness of mankind.

Dr Simmons's life and its broad activities have been described in *THE JOURNAL*. It remains for the Council to consider more particularly that phase of his work whereby he sought successfully to promote rational scientific therapeutics.

Thirty years ago one often heard the statement that the therapeutic use of drugs was in a state of chaos. This condition arose partly because the rapid strides that had been made in chemistry and biochemistry, pathology and pharmacology outran the capacity of the average physician to distinguish real progress from the absurd and often fraudulent reports of pretended advances which filled so large a part of the medical literature of that day.

Commercial interests did not create the condition, but they strove mightily to profit by it. Simmons and other leaders in medicine early became deeply concerned with the need of introducing system in place of the general confusion. With this end in view, Simmons in consultation with other broad-minded men organized the Council on Pharmacy and Chemistry, with the primary object of protecting the advertising pages of *THE JOURNAL*, which under his direction had become the foremost weekly medical journal of the United States, later of the world.

Simmons was well aware that this course would involve the enmity of powerful financial interests that were thriving on existing conditions. Ten years after the organization of the Council he stated in an address before the Southern Medical Association that the task which the Council had undertaken included the solving of problems so difficult that they seemed impossible of solution, that the work appeared, as it proved to be, stupendous, and that the members of the Council had been ridiculed and even slandered in the beginning. After enumerating many fraudulent, useless or even dangerous preparations which had been driven virtually, or completely, out of existence, he stated that not a single nostrum had been introduced successfully to the physicians of the country after the inauguration of the Council, whereas previously there was hardly a week—certainly not a month—in which at least one was not foisted on the medical profession. That address with its enumeration of changes which had already taken place may well be astonishing even to members of the Council today.

Simmons proceeded with great skill to secure the cooperation of the better class of manufacturers, to many of whom he proved not only that honest advertising was practicable but that it was more profitable. He then broadened the scope of the work of the Council, which undertook the consideration of many therapeutic problems not directly concerned with the original purpose for which the Council was organized and he was able to secure the active participation of many of the foremost teachers of medicine in the United States and of some living abroad. Simmons builded better than he knew or possibly in his modesty he did foresee the constantly expanding nature of his work, and those who have followed his career are agreed that he did more—directly and indirectly—for the progress of medicine than any other man of his time.

It has been said by one long closely associated with Simmons that his founding of the Council on Pharmacy and Chemistry, his active participation in all its work, his support through many trying battles, may appear but a trivial insignificant fraction of so great and extensive a career; nevertheless the Council seemed nearest to his heart.

because his keen intuition saw that it was the way to the solution of problems of fundamental honesty, scientific achievement and practical progress that affect the daily life of every physician. We of the Council shall miss the contagion of his enthusiasm and the warmth of his friendship.

Every member of the Council on Pharmacy and Chemistry joins in this expression of sorrow at the passing of one for whose many fine qualities they have the highest admiration and whom they have long held in deep affection.

We may well say of Simmons, as he wrote of another member of the Council on such an occasion as this: "In his death the Council has lost a member of unique value, *THE MEDICAL PROFESSION* a servant who served it faithfully."

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

SALYSAL, A NONPROPRIETARY NAME

Rare Chemicals, Inc., Nepera Park, N. Y., presented for the Council's consideration the salicylic acid ester of salicylic acid under the name of Salysal. The name Salysal was proposed because Diposal, the name under which the preparation was introduced, is owned and controlled by the Chemical Foundation. The firm also indicated its willingness to consider any suggestion from the Council as to what the preparation should be called if Salysal were not satisfactory. The Council informed the firm that it could not recognize the firm's right to a proprietary name but that it was willing to consider the alternative suggested by the firm, its relinquishment of proprietary rights in the term Salysal. In reply, Rare Chemicals, Inc., formally relinquished its exclusive rights to the name Salysal. The Council, therefore, adopted Salysal as a nonproprietary name for the salicylic ester of salicylic acid.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES BY WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

SALYSAL.—The salicylic ester of salicylic acid— $\text{HO.C}_6\text{H}_4.\text{COO.C}_6\text{H}_4.\text{COOH}$

Actions and Uses.—Salysal provides the antipyretic and analgesic effects of the salicylates. Being insoluble in water and dilute acids, it is relatively free from disagreeable taste and local irritating action. The toxicity of salysal is relatively low and is no greater than that of acetylsalicylic acid or sodium salicylate on the basis of salicylic acid content.

Dosage.—From 5 to 10 grains (0.3 to 0.6 Gm.) two to three times a day. Salysal is approximately twice as active therapeutically as sodium salicylate and may be employed in one half the dosage of the latter drug.

Manufactured by Rare Chemicals, Inc., Nepera Park, N. Y., U. S. patent No. 922,995 (May 25, 1909, expired). The firm has relinquished trademark rights to the name salysal.

Salysal Tablets 5 grains (0.3 Gm.)

Salysal is a white crystalline odorless and tasteless powder. It melts at 149° C. (Kofler micro melting point apparatus). Salysal is soluble in alcohol (ether) and alkalis; it is insoluble in water and dilute acids.

Shake salysal with cold water and filter. Separate portions of the filtrate do not yield a violet color on addition of ferric chloride test solutions or become cloudy on addition of silver nitrate test solution. Dissolve 0.05 Gm. of salysal in 1 cc. of normal potassium hydroxide solution and add 1 cc. of normal sulfuric acid and dilute with 5 cc. of water. On addition of 1 drop of ferric chloride test solution a deep violet color is produced.

(a) Incinerate a weighed amount of salysal; the residue is not more than 0.03 per cent.

(b) The moisture content is not more than 0.5 per cent. Dissolve 0.5 Gm. of salysal previously dried at 100° C. for two hours and accurately weighed in 50 cc. of diluted alcohol which has been previously neutralized with tenth normal sodium hydroxide. Add 1 cc. of phthalein test solution as indicator. Add to this 50 cc. of tenth normal sodium hydroxide and reflux for one hour. After cooling to room temperature titrate the excess alkali with tenth normal hydrochloric acid. The difference is the number of cubic centimeters of tenth normal hydrochloric acid required to neutralize the salicylic acid ester present in the tenth normal sodium hydroxide. Calculate the amount of salysal in the sample not be less than 99 per cent.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
FRANKLIN C BING Secretary

THE NUTRITIONAL VALUE OF SPINACH

Spinach, kale, turnip tops, beet leaves and other green leafy vegetables have long been considered as particularly desirable components of the diet because of their content of certain vitamins and minerals. Of these foods, spinach (*Spinacia oleracea*) has perhaps been most extensively studied.¹ The cooked leaves of this plant have been used as a food for centuries. At the present time this food is available commercially in a variety of forms. Fresh spinach can be purchased in the metropolitan markets of the United States at all seasons of the year. So called quick frozen spinach is becoming more readily obtainable in metropolitan centers. The canned product, including sieved spinach, can be purchased anywhere and several brands of the latter have been accepted by the Council as foods that are useful in infant feeding. Dried powdered spinach also can be purchased, and it is obtainable in tablet form, one brand has been accepted.

With the development of our knowledge of nutrition, the value of green leafy vegetables received special attention, and spinach, so readily obtainable throughout the year, was emphasized as typical of such foods. While some of the supposed nutritive properties of spinach are now known to be nonexistent, still other properties are well established, and spinach should continue to be regarded as a wholesome food. The present report provides a review of existing information regarding the composition and nutritional significance of spinach.

COMPOSITION

Raw Spinach—In the accompanying table is presented the average composition of fresh spinach according to the older analyses reported by Atwater and Bryant² plus some more recent data. These figures show that spinach is relatively rich in ash and in fiber compared to total solids. They also show that this food would be included in lists of vegetables lowest in carbohydrates as used in the planning of diets for diabetic patients.

The average vitamin content of fresh spinach has been calculated by Daniel and Munsell³ to be per hundred grams, 35,000 U. S. P. units of vitamin A, 30 International units of vitamin B₁, 800 International units of vitamin C and 125 Sherman Bourquin units of vitamin G. Raw spinach, therefore, contains an extraordinarily high concentration of vitamin A (provitamin A) and is rich in vitamin C.

Analyses show also that spinach is a vegetable food which is particularly high in iron and calcium. It also contains a fair amount of copper. The total iron content has been reported to be from 17 to about 3 mg. of iron per hundred grams of fresh leaves.⁴ The calcium content has been estimated by Sherman⁵ to be on an average about 0.067 per cent, values as high as 0.13 per cent have been reported. The copper content of spinach is variable but may be expected to be in the neighborhood of 0.12 mg. per hundred grams.⁶ According to these figures obtained from chemical analysis, spinach would be rated as a good source of calcium and an excellent source of iron and, although the human requirements for copper are not known with any degree of precision it is a relatively good source of copper. Further on in this report evidence will be

discussed which indicates that spinach is not as good a source of dietary iron and calcium as these quantitative values would indicate.

Other substances have been reported to occur in spinach. Perhaps the most important of these from the dietary point of view is oxalic acid. Values of from 0.29 to 0.82 per cent have been found for the fresh leaves.⁷ These figures show that spinach is a food which is relatively high in this substance. The oxalic acid is present in the form of its salts—calcium oxalate and other oxalates, and possibly as free oxalic acid. Traces of citrates and malates also have been reported.⁸

The carotene of spinach has been studied by a number of investigators.⁹ It appears from their work that practically all the carotene (provitamin A) is in the form of optically inactive beta carotene. The nature of the proteins¹⁰ and of the ether extract¹¹ of spinach has also been investigated. The presence of two new sterols in the nonsaponifiable fraction has been reported. While these and other investigations on the components of spinach are of great interest for the purposes of the present article they need not be discussed further.

Variations in Composition—As in the case of most plant materials the quantitative composition of spinach is variable.

Average Composition of Raw Spinach

	per cent
Moisture	92.3
Protein (N x 6.25)	2.1
Fat (ether extract)	0.3
Total carbohydrate	3.2
Crude fiber	0.9
Ash	2.1
Calcium as Ca	0.067
Iron as Fe	0.0025
Vitamin A	35,000 International units per hundred grams*
Vitamin B ₁	30 International units per hundred grams
Vitamin C	800 International units per hundred grams
Vitamin G	125 Sherman units per hundred grams

* Mary S. Rose (A Laboratory Handbook for Dietetics, ed. 4, New York: Macmillan Company, 1937) used the median value from the best reported data and has estimated the vitamin A content of spinach to be somewhat lower or 25,000 International units per hundred grams.

References to the following studies will show the scope at least of some of the work which has been reported on this subject. The vitamin C content of different varieties of spinach,¹² the effect of different soils and the influence of fertilizers on the amount of vitamin C in spinach,¹³ the effect of weather conditions on the composition of spinach grown in India,¹⁴ and variations in the mineral content of spinach grown in the Orient¹⁵ and in Maryland and Virginia¹⁶. It has been sug-

gested that the composition of vegetables might well be thought of as a range of values rather than as any fixed value.

More important than variations in the composition of the fresh leaves of spinach is the effect of various treatments concerned with the preparation of the dish that is eaten. Some information is available on the vitamin C content. It has been shown by a number of workers that the amount of vitamin C in the leaves of fresh spinach diminishes rapidly when standing at ordinary temperatures and becomes vanishingly small five or six days after the leaves have been cut.¹⁷ Storage at refrigeration temperatures and storage in the absence of oxygen retard the rate of loss.

The effect of cooking on the nutritive value of vegetables has been studied by a number of workers and it is well known that the effects vary somewhat depending on the method of cooking. Comparatively few quantitative data are available regarding the vitamin content of cooked spinach. Considerable work is being done on these problems, particularly in university departments of home economics and in government bureaus, and because of their practical importance such investigations should be encouraged. As far as available information goes it appears that the cooking of spinach may leach out considerable amounts of salts and water soluble vitamins and may result in the destruction of considerable amounts of vitamins B₁ and C.¹⁷ There also may result some destruction of vitamin A and vitamin G.

Cooked spinach usually is considered as an excellent source of vitamin A, a fairly good source of vitamin C, and a contributor of iron and bulk to the diet.¹⁸ Canned spinach has been considered to have about the same nutritional values as fresh cooked spinach. On the other hand, the drying of spinach ordinarily results in the practically complete destruction of vitamin C, although the vitamin A can be retained to a much better degree and dried spinach rates as an excellent source of this vitamin. A recent report by Fellers and his associates¹⁹ at the Massachusetts Agricultural Experiment Station provides information about the effect of several processes on the amounts of vitamin A and vitamin C. Colorimetric determinations of the provitamin A content gave the following values, expressed as micrograms of carotene per gram of dried weight: fresh leaves 430, blanched and frozen 358, canned spinach 283, and dehydrated 310. Expressed in International units of vitamin A per gram of dried material, these values are: fresh spinach 7,250, blanched and frozen 3,880, the canned product 6,000 and the dehydrated 520. Thus, spinach in all these forms would rate as an excellent source of vitamin A.

According to this report by the Massachusetts investigators, titration with 2,6-dichlorophenolindophenol of the vitamin C content of spinach gave results in close agreement with the bio-assay method. The fresh leaves contained from 0.38 to 0.77 mg of vitamin C per gram. Of the original vitamin C content, spinach lost the following amounts, expressed in percentages of the original value: on cooking, 48, on blanching and freezing, 40, after canning, 60, on dehydrating, 100. These figures show that canned or cooked spinach is a fairly good source of vitamin C (whereas the fresh leaves are an excellent source) and dehydrated spinach contains none of the anti-scorbutic factor.

NUTRITION STUDIES

Vitamins—While knowledge of the chemical composition of a food is important, conclusive evidence regarding the nutritional value of any food can be obtained only by feeding experiments. The vitamin content of spinach has been determined by animal assays, and therefore the reported values indicate the actual availability of this food as a source of each vitamin so determined.

Iron—Chemical examination for the total iron content of spinach indicates that it is one of the richest plant sources.

thus dietary essential. The evidence now is clear, however, that not all the iron of spinach is available to the organism. Tests for inorganic iron by the dipyriddy method have shown that only 20 per cent of the total iron is ionizable or "available" iron.²⁰ Later workers have found somewhat different values. Shackleton and McCance²¹ reported that 60 per cent of the total iron of spinach is ionizable. Horwitt, Cowgill and Mendel,²² using a method involving treatment with enzymes in imitation of conditions in the intestinal tract, found that 40 per cent of the iron of spinach could be brought into solution and, according to their criterion, could be considered as available. It would be of interest to know the nature of the unavailable iron which these reports would indicate is present in such large concentrations in spinach.

Elvehjem and his co-workers²³ have also checked the chemical determinations of inorganic iron against the biologic assay for available iron. They found that anemic rats responded (by increases in hemoglobin concentration of the blood) to the feeding of spinach to a degree which might be expected if about four fifths of the total iron was unavailable. Earlier reports by Mitchell and Schmidt²⁴ and by Levine, Culp and Anderson²⁵ indicated that the iron of dried spinach is well utilized. However, their experimental animals received 0.4 mg of iron daily, which was sufficiently above the level of intake required by the anemic rat to obscure large differences in availability of spinach iron as compared to inorganic iron salts. Rose, Vahlteich and MacLeod,^{26a} feeding cooked spinach or powdered dried spinach to yield 0.1 milligram of iron daily, found that hemoglobin regeneration in rats was about the same as with an equivalent amount of iron in the form of liver, approximately 50 per cent.

Metabolism studies with infants likewise have shown that spinach is not as good a source of iron as chemical analysis would indicate. The most complete report has been provided by Stearns and Stinger.²⁶ These workers fed infants a basal diet of cows' milk, carbohydrate and orange juice. They then determined the effect on the iron metabolism of small additions to the diet of spinach, egg yolk, a cereal preparation containing added iron salt and an iron salt itself. On the basal diet the infants lost an average of 0.05 mg of iron daily regardless of age (the fourteen infants studied varied from 7 to 54 weeks of age). The feeding of spinach and the feeding of egg yolk did not increase the retention of iron, probably because the iron intakes were too small. The amount of iron retained by the body was definitely increased, however, when the infants were given the cereal mixture containing added iron salt or when they were given ferric ammonium citrate. The amount of spinach fed, it is true, was not great enough to increase the iron intake materially, but the average iron loss of the infants studied was greater when feedings of spinach were administered than when the milk formula alone was given. In the experiments of Schlutz, Morse and Oldham,²⁷ the iron intakes of the infants were increased from 60 to 170 per cent above the level of the basal diet, but these investigators observed no significant increase in the retention of iron.

It may be concluded from these observations that, as far as its practical usefulness as a source of iron in the feeding of infants is concerned, spinach is of negligible value because little

of it can be fed. However, even though all the iron of spinach may not be available, the total iron content is great enough for spinach to rate as a good source of iron for older children and adults. But direct experimental evidence is not now available to enable one to arrive at any conclusion regarding the precise value of spinach as a source of iron for persons beyond the age of infancy.

Calcium—Though spinach is one of the few plant foods rich in calcium, evidence has accumulated that this calcium is not available to the organism. Many years ago McClugage and Mendel²⁸ found that the calcium of spinach was poorly utilized by dogs. In 1922 Sherman and Hawley²⁹ observed that the calcium balances of children from 3 to 13 years of age were more variable and less favorable when half the milk of the diet was replaced by a mixture of vegetables so selected as to equal the calcium content of the milk omitted. The vegetable mixture fed consisted of spinach and carrots with or without celery or string beans.

On the other hand, Blatherwick and Long³⁰ concluded that the calcium of spinach and also of some other vegetables could be satisfactorily utilized by young women. McLaughlin³¹ in 1927 reported results of some experiments in which for six days she fed spinach as the only food high in calcium to young women. The calcium balance was distinctly positive in six of the subjects and calcium equilibrium was maintained in the seventh. The spinach furnished 70 per cent of the dietary calcium, but, as Sherman has pointed out, the calcium intake was above the maintenance level. It is difficult to interpret the results of any metabolism studies with calcium, particularly if the calcium intake on the basal diet is sufficiently high to result in a positive balance. The evidence does show, however, that the inclusion of spinach in a good diet does not adversely affect the calcium balance of adults.

In 1930 Bloom³² reported her experiments with animals. She fed rats diets that were similar in their concentration of calcium and phosphorus but contained variable amounts of dried raw spinach or dried cooked spinach. Low retentions of calcium and phosphorus were observed on the spinach diets. When the ash of the spinach was fed, rather than the dried leaves, the retentions were higher, even when filter paper was added. The poor availability of the calcium of spinach, therefore, could not be attributed entirely to the roughage of the diet, as Mendel and McClugage had supposed from their results with dogs.

One reason for the poorer availability of the calcium of spinach has been made clearer by the observations of Kohman³³. He reported that as was then already known, ordinary spinach contains about 0.5 per cent of oxalic acid, which is a relatively high amount, although not as high as the oxalate content of a few other foods. Plant histologists have long recognized that much of the calcium of leaves is present in the form of the highly insoluble calcium oxalate. Large characteristic crystals of this substance may be seen on sectioning the leaves of spinach. In feeding experiments with rats, Kohman and Sanborn³⁴ found that the availability of calcium in calcium oxalate is low. Furthermore the presence of soluble oxalates is detrimental because calcium which is otherwise available is rendered unavailable by the presence of these salts. Fineke and Sherman³⁵ in 1935 reported the results of feeding experiments with rats. They found that the calcium of dried spinach was utilized poorly if at all. In contrast, the calcium of kale, a plant which is relatively poor in oxalates, was nearly as well utilized as the calcium of milk. The report by Horwitt, Cowgill and Mendel³⁶ is also of interest in this connection. By means of

an enzymatic digestion method they were able to show that only 30 per cent of the calcium of dried spinach could be brought into solution and hence could be considered available.

That the calcium of spinach is poorly utilized by young infants was reported in 1931 by Edelstein, Langer and Langstein³⁶. Further observations were reported by Edelstein³⁷ in the following year. Schlutz and his co-workers³⁸ likewise concluded that the influence of vegetable feeding on the mineral retention of young infants is negligible and that the addition of spinach actually leads to a slightly decreased retention of calcium. Stearns and Stinger³⁹ found that the calcium retention of infants fed a diet of cow's milk amounted to 35 per cent of the calcium intake but that this fell to 27 per cent of the intake during the time when spinach was fed. They observed that the feeding of spinach to infants appears to be more detrimental than beneficial (as far as calcium and iron are concerned). It may be concluded that there is no evidence that the calcium of spinach is available to young infants and that, indeed, the feeding of spinach may decrease slightly the retention of this element.

More recently Maey and her collaborators³⁹ have reported the results of an extended study of the metabolic balance of calcium on ten growing children. The data obtained by these authors are especially noteworthy because of the care with which the work was done and the relatively long periods in which the children were observed. No untoward effects were observed as a result of adding spinach, or oxalic acid in amounts equal to that contained in the spinach, to the control diet. They found that the rate of storage of calcium, as well as of nitrogen and phosphorus, was not significantly altered by the daily consumption of as much as 100 Gm of spinach. Slight variations in retentions were noted but, as the authors pointed out, these were not incompatible with the usual variations that may be observed during growth. The rate of growth, or storage as one might call it, of calcium in the bodies of these young children was not altered, apparently because the diet was high enough in calcium to overcome any deleterious effect of the oxalic acid of the spinach and still provide for the fluctuating growth needs. As the Detroit investigators have already emphasized, one should not consider spinach apart from the composition of the rest of the diet. Because of its richness in vitamin A, iron and other nutritive essentials, spinach may well retain its customary place along with other leafy vegetables in the diet of children and adults.

SUMMARY AND CONCLUSIONS

From the evidence available, spinach may be regarded as a rich source of vitamin A and as a contributor of vitamin C, iron and roughage to the diet. It is therefore a valuable food.

While the total iron content of spinach is high as compared with other vegetable foods, the evidence shows that this iron is not wholly available and is not well utilized by infants. Evidence regarding the amount of the iron of spinach that is available to older children and adults has not been reported at the present time.

The calcium of spinach is not well utilized by the organism because it is present largely in the form of calcium oxalate, which is insoluble in the fluids of the alimentary tract. Soluble oxalates which are likewise present may interfere with the absorption of the calcium of other foods because of the precipitation of calcium oxalate in the intestine. Metabolism experiments show that the feeding of spinach is of no value during early infancy as a source of calcium; there is, of course, plenty of calcium in milk to meet the needs of normal infants. The evidence also shows that in young children and in adults receiving diets adequate in calcium content the inclusion of spinach does not adversely affect the calcium metabolism.

PNEUMONIA MORTALITY AND PNEUMOCOCCUS TYPING FACILITIES

In a recent study by Kenneth McGill¹ of pneumonia mortality, he found about 96,500 deaths a year from pneumonia during the period from 1930 to 1935. This represents an average annual rate of 77 per hundred thousand and places pneumonia fifth as a cause of death. If it should be combined with influenza, however, the average annual rate would be 100, thus placing this group near cancer, close to second place.

On the basis of experience in the last six years, chance of a given death being due to pneumonia is approximately one in fourteen. Pneumonia mortality is highest among the young and the very old, higher among males than among females, and higher among Negroes than among white persons. Excessive pneumonia mortality rates occur in certain industries. The 1935-1936 health surveys of eight cities, based on a house to house campaign, indicated that sickness from pneumonia varies inversely with the family income.

Most of the cities with high annual pneumonia death rates per hundred thousand for the years 1929-1931 are located in the southwestern or northwestern parts of the country. Among the cities of 100,000 and over, Pittsburgh has by far the highest rate, 217, and Long Beach, Calif., the lowest, 42. If the cities are listed according to their rates, Kansas City, Kan., whose rate is 100, stands at the midpoint between Pittsburgh and Long Beach.

At least 85 per cent, or 500,000, of the pneumonia cases estimated as occurring each year are caused by pneumococci. Types I, II, III, V, VII and VIII are the most common types and probably account for about 70 per cent of the cases and 85 per cent of the deaths that are due to pneumococci. All but type VIII appear to have high fatality rates. Antipneumococcus serum is available for types I and II, which are estimated

to cause 175,000 cases and 38,000 deaths annually. Serums, promising but not generally employed, have also been developed for types V, VII and VIII, which annually cause an estimated 100,000 cases and 21,000 deaths.

In view of this distribution of pneumonia and the known effectiveness of serum when given early in the most fatal types, the facilities for typing are of the utmost importance. The health departments of thirty-one cities have main or branch laboratories equipped for the typing of pneumococci. Only twenty-seven, however, have employees engaged either full or part time in typing. Furthermore, the laboratories of only twenty-one cities did any typing during 1936. These twenty-one laboratories, however, typed almost 9,800 specimens, secured 6,200 positive reactions and identified the type I pneumococcus 1,200 and the type II pneumococcus 340 times. All but approximately 11,000 specimens were typed by three states, New York, Michigan and Massachusetts, all of which have pneumonia control programs. The Southwest and South east, which in common with the Northeast have high death rates, have much less equipment and practically no activities in typing. Most of the health departments of the ninety-three cities of 100,000 and over operate their own laboratories, but ten depend on contract arrangements. Under these conditions, sixty-one cities possess equipment for typing by the Neufeld rapid method and thirty also have equipment for other methods. Only fifty-one, however, have employees engaged in typing, and only thirty-nine of these actually did any typing during 1936. The thirty-nine city laboratories that were active in 1936 typed 9,227 specimens. Furthermore, seventeen of these cities were participating in the control programs of Connecticut, Massachusetts, Michigan or New York and were responsible for 78 per cent of all specimens typed during that year.

In a questionnaire postcard sent out by the American Medical Association to survey "hospital" laboratory facilities for pneumococcus typing, 2,595 replies were received from 4,565 hospitals. Of 2,595 hospitals, 1,850 were equipped for pneumococcus typing, of which number 1,767 used the Neufeld method. Relatively little regional difference in the percentage of equipped hospitals, however, was evident from this survey. In most of the states, from 30 to 70 per cent of the hospitals recorded facilities.

The high death rate from pneumonia and the large percentage falling in the group of known response to specific serum make it evident that this means of therapy is not adequately employed. Equipment for typing does not necessarily mean that typing is being done on any such scale as is actually indicated. These surveys disclose the inadequate equipment for pneumococcus typing of some communities and indicate their lack of proper utilization in others.

MEDICINE IN RUSSIA

In a book entitled "Socialized Medicine in the Soviet Union," just published by Henry E. Sigerist,¹ William H. Welch professor of the history of medicine at Johns Hopkins University, he makes the following statement

Nobody can deny that Soviet medicine, in the short period of twenty years and under most trying circumstances, has stood the test and has created powerful measures for the protection of the people's health. It has demonstrated that socialism works in the medical field too, and that it works well, even now, in the early beginnings of the socialist state. It is a system that is full of promise for the future—for a very near future.

In his preface Dr. Sigerist points out that he has spent two summers in Russia and that he has had the aid of leading authorities in the development of his information. He states that he has not wasted time in describing the poor institutions but that he has been primarily interested in the principles of Soviet medicine and in those positive achievements which represent a permanent gain.

At the same time there appears a book entitled "Assignment in Utopia" by Eugene Lyons,² who was for some seven years the United Press representative in Russia. He was sent to Russia because he had been known in this country as a communist and because his appointment was acceptable to the Russian government. He was probably the first to interview Stalin. As the seven years passed he gradually changed his point of view so that eventually he left Russia at the request of the government. In his book, based on seven years of life in Russia from 1930 to 1937, he reflects in four and one-half pages his personal observations of medicine in Russia. He says

We came, unluckily, to know a lot more about Soviet medical practice than most of our colleagues. Like the "stable" currency and the wonderful educational methods, the socialized medicine under the official statistical surface was a snarl of contradictions, shortages, and ineptness. Doctors and dentists regarded their obligatory work for the state as an exaction and depended on private practice for their real income. The more famous medical specialists did not budge for less than fifty or a hundred rubles, often it required "pull" to get their services at any price. The public health service was by all odds inferior to the free public and charitable health services available to the poor in cities like New York or Chicago.

Mr. Lyons describes the experience of his wife, who became ill and who was taken to Botkinsky Hospital. This section concludes

Billy improved rapidly despite the special care, and was soon well enough to watch the conduct of that hospital by way of sociological diversion. If I had not been there day after day and seen some of the primitive and careless procedure myself, I should have thought the details she told me were the effects of delirium. Only a few of the women were trained nurses—the others were ignorant girls of the servant type. They stomped up and down corridors and banged doors and called for one another in loud voices. Except under unusual circumstances bed linens were changed once a week. The blankets were not washed but merely disinfected so that they were crusted with the dirt and vomit of previous patients. The precious rules prohibited the bringing of linens, blankets, or other accessories from outside. But by devious means I smuggled in everything

Billy needed, and doctors, nurses, patients came to her ward to inspect and exclaim over the fleecy American blankets, the hospital buzzed with the news of a foreigner who changed her sheets, her nightgown, and even her pillow-cases, every day.

The doctors, Billy thought, were capable but overworked. I succeeded—again by outraging the blessed rules—in having our own physician, who was familiar with her case, treat her. As soon as she could be moved safely she returned home.

Ever after, the glowing reports of socialized medicine in Russia in American books and magazines have been a source of amusement to us. Always we have wished their authors only one punishment—a week or so as patients in the second-best hospital in Russia.

This book contains not only innumerable dramatic incidents but in addition some humorous descriptions of the visits of average American tourists to Russia which indicate how much value may be attached to their reports.

Dr. Sigerist is an experienced medical historian. He is also firmly committed to socialized medicine and to a planned and regimented economy. Certainly the world may learn much from the "Russian Experiment," but it is perhaps more scientific at present to consider it still as just an experiment and not as definite evidence of the established value of the Russian system of medical care.

SAFEGUARDS PROPOSED TO GOVERN
DISTRIBUTION OF DANGEROUS
DRUGS

Senator Copeland of New York and Representative Chapman of Kentucky have elicited from the Secretary of Agriculture a report on recent deaths resulting from the use of elixir of sulfanilamide-Massengill. The report shows a total of seventy-three deaths which have been confirmed and twenty which were presumptively due to the use of that preparation. The essential facts in the report, submitted to Congress by the secretary November 26, are already familiar to all who have read recent issues of *THE JOURNAL*.¹ The report includes four recommendations as follows:

1 License control of new drugs to insure that they will not be generally distributed until experimental and clinical tests have shown them to be safe for use. The definition of what constitutes a new drug should include (a) substances which have not been used sufficiently as drugs to become generally recognized as safe, (b) combinations of well known drug substances where such combinations have not become generally recognized as safe, and (c) well known drug substances and drug combinations bearing label directions for higher dosage or more frequent dosage or for longer duration of use than has become generally recognized as safe.

Exemption should be made for new drugs distributed to competent investigators for experimental work. A board of experts should be provided who will advise the Secretary of Agriculture on the safety of new drugs.

2 Prohibition of drugs which are dangerous to health when administered in accordance with the manufacturer's directions for use.

3 Requirement that drug labels bear appropriate directions for use and warnings against probable misuse.

4 Prohibition of secret remedies by requiring that labels disclose fully the composition of drugs. Many foreign countries

¹ Sigerist, Henry E. *Socialized Medicine in the Soviet Union*. New York: W. W. Norton & Co. 1937. p. 98.

² Lyons, Eugene. *Assignment in Utopia*. New York: Harcourt Brace & Co. 1937. pp. 437 and 440.

¹ Deaths following Elixir of Sulfanilamide Massengill. editorial *J. A. M. A.* 109:1367 (Oct. 23) 1456 (Oct. 30) 1544 (Nov. 6) 1727 (Nov. 20) 1937. Elixir of Sulfanilamide Massengill. Special Article from the American Medical Association Chemical Laboratory. *ibid.* 109:131 (Nov. 6) 1724 (Nov. 20) 1937.

now impose this requirement. Many drugs manufactured in the United States are exported to such countries under labels bearing such disclosure. The same drugs are sold to our citizens under labels that give no hint of their composition.

In view of the resolutions in response to which the Secretary of Agriculture submitted his report, the recommendations were limited to conditions relating to drugs and secret remedies. It is presumed however that, in drafting legislation to carry into effect those recommendations, something will be done to prevent poisoning due to the use of untried chemicals in foods and beverages, recent examples of which were the presence of tricresyl phosphate in Jamaica ginger and of wood alcohol in products intended for beverage purposes.

The recommendations of the Secretary of Agriculture may well form the basis of both federal and state legislation. Licensing, however, is for the protection of the public at large and should be paid for by general taxation and not by licensing fees, which the manufacturer would add to the cost of his product and thus add to the burden of illness. Resort to licensing and registration for the protection of public health is now an established procedure in federal and state governments, and it is within the discretion of Congress and the state legislatures to determine when, where and how that procedure shall be adopted. As long ago as 1895, Congress made licensing a condition precedent to the importation of milk from any state into the District of Columbia for sale. In 1902 a license was made a condition precedent to the importation of biologic products into the United States for human use and to the shipment of such products in interstate commerce. In 1913 the same licensing and registration principle was applied to the importation and shipment of biologic products for veterinary use. Even now there is pending in the House of Representatives a bill proposing to apply licensure as a condition precedent to the shipment in interstate and foreign commerce of surgical ligatures and sutures. The principle is recognized in bills pending in Congress as necessary for the protection of the public against contaminated foods under some conditions, and it is proposed that the Secretary of Agriculture be authorized to make such licensing necessary whenever in his judgment circumstances require it. A bill to that effect has passed the Senate and is pending in the Committee on Interstate and Foreign Commerce of the House of Representatives.

Licensing and registration legislation is preventive and not curative. It recognizes that damages recovered by civil suits of persons injured and imprisonment of offenders on the initiative of prosecuting attorneys do not recompense victims for their sufferings or return them to conditions of usefulness. Effective protection may be established by licensure or registration based on the adequacy of plant, equipment and material, the competence of the personnel and on the soundness of the value of methods or procedures.

manufacturer, distributor and seller must be fully responsible for any claim he makes as to the properties of his product and the government should not be "placed on the spot" by issuance of licenses which may be interpreted as endorsements or by laws requiring submission by manufacturers of confidential information.

The four requirements suggested by the Secretary of Agriculture are much to the point. Unless some more effective method than licensing is proposed—and none has yet been offered—legislation looking toward licensing or registration in association with full disclosure of formulas should be promptly enacted to protect the public against incompetent or unscrupulous purveyors of drugs.

A NOBEL PRIZE FOR SZENT-GYORGYI

Dr. Albert Szent-Gyorgyi of the University of Szeged has been named as 1937 Nobel prize winner in medicine for his contributions to the subject of biochemical oxidations and for outstanding work on the isolation and identification of vitamin C. After the World War, Szent-Gyorgyi, a Hungarian army medical officer, decided to devote his life to biochemical research. Several years later while working in Cambridge, England, he published an account of the isolation of a crystalline substance from adrenal tissue and from several plant products. There was reason for supposing that this newly discovered substance might be important in the oxidation-reduction systems of both plant and animal tissues. A solution of Szent-Gyorgyi's crystals had strong reducing properties, silver nitrate solution was acted on at room temperature to give a black precipitate of metallic silver. Because this reducing compound was a derivative of a sugar having six carbon atoms it was named "hexuronic" acid. Not until six years later was it shown that hexuronic acid is identical with vitamin C. The elucidation of the nutritional importance of hexuronic acid was largely the result of intensive work on the isolation of the antiscorbutic factor from lemon juice by King and his collaborators at the University of Pittsburgh. From a potent concentration of lemon juice an active crystalline product was obtained, the antiscorbutic potency of the crystals was unchanged by repeated crystallization, finally, the crystals were proved identical with hexuronic acid. From Szent-Gyorgyi's laboratory came an account of the identification of vitamin C with hexuronic acid. The pure vitamin has been synthesized. The older name hexuronic acid has been discarded and vitamin C is now known as ascorbic (ascorbic) acid. Recently Szent-Gyorgyi postulated the existence of another vitamin in foods. This factor appears to be closely associated with vitamin C but is not identical with it. The new vitamin is concerned with the permeability of the capillaries and it has been named vitamin P. The bestowal of a Nobel prize on Professor Szent-Gyorgyi is a fitting reward for his notable contributions to biochemistry and medicine.

Association News

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago Feb 14 and 15, 1938. The Federation of State Medical Boards of the United States will participate in the congress. The program follows:

MONDAY MORNING, FEBRUARY 14

Report of the Council on Medical Education and Hospitals

Ray Lyman Wilbur MD LL.D. Chairman Stanford University Calif

Professional Licensure

John Kirkland Clark Counselor at Law New York

The Role of Chemistry in Medicine

Reverend Alphonse M. Schwittalla SJ Ph.D. Dean St. Louis University School of Medicine St. Louis

The Functions of the Special Examining Boards

Willard C. Rappleye MD Dean Columbia University College of Physicians and Surgeons New York

MONDAY AFTERNOON, FEBRUARY 14

Limiting Student Enrollment

Walter M. Kotschnig Ph.D. Smith College Northampton Mass

An Introduction to Clinical Medicine and Some Variations in the Curriculum of the Third and Fourth Years in Medical School

Burrell O. Raulston MD Professor of Medicine University of Southern California School of Medicine Los Angeles

Medical Student Instruction in Preventive Medicine

J. G. Fitzgerald MD Director School of Hygiene and Connaught Laboratories University of Toronto Toronto Canada

A New Approach in the Teaching of Nutrition to Medical Students

Salvatore Pablo Lucia MD Assistant Professor of Medicine and Lecturer in Medical History and Bibliography University of California Medical School San Francisco

Some Aims and Methods of Undergraduate Teaching in Obstetrics

James R. McCord MD Professor of Obstetrics and Gynecology Emory University School of Medicine Atlanta Ga

TUESDAY MORNING, FEBRUARY 15

SYMPOSIUM ON GRADUATE MEDICAL EDUCATION

John H. Musser MD Professor of Medicine Tulane University of Louisiana School of Medicine New Orleans

Irvin Abell MD President Elect American Medical Association Louisville Ky

James D. Bruce MD Director Department of Postgraduate Medicine University of Michigan Ann Arbor

Lester J. Evans MD Medical Associate The Commonwealth Fund New York

Arthur C. Bachmeyer MD Associate Dean School of Medicine of the Division of Biological Sciences University of Chicago

THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

TUESDAY MORNING, FEBRUARY 15

(Program to be announced)

JOINT SESSION WITH THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

TUESDAY AFTERNOON, FEBRUARY 15

American Students in Italian Medical Schools

William C. MacTavish AM Adviser to Premedical Students New York University Washington Square College New York

Foreign Students

Charles B. Pinkham MD Secretary California Board of Medical Examiners Sacramento

Hospital Internships as a Requirement for State Registration

Winford Smith MD Director Johns Hopkins Hospital Baltimore

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs, beginning Oct 13 1937, and running weekly through June 15, 1938. The programs will be presented over the Red network each Wednesday at 2 p.m. eastern standard time, 1 p.m. central standard time, 12 o'clock noon mountain standard time and 11 a.m. Pacific standard time.

The dates and topics of the broadcasts for the coming month are as follows:

Diet

December 8—It Takes All Good Foods a well rounded diet and how to get it

December 15—Vitamins Minerals and Common Sense more about a balanced diet in special relation to minerals and vitamins

December 22—Milk from Farm to Table the production, transportation, pasteurization and home care of milk, its place in the diet, processed milks

December 29—Dietary Fads facts vs fallacies in relation to prevalent false notions on diet

The stations on the Red network are privileged to broadcast the program but, since it is a noncommercial program, they are not obligated to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Personal—Dr. Charles M. Cole, Chatom, has been appointed health officer of Washington County, succeeding Dr. Isaac C. Sumner, Chatom, who has been named assistant to the health officer of Mobile County, it is reported.—Dr. Eva F. Dodge, Winston-Salem, N. C., will direct and organize antepartum clinics throughout Alabama for the state department of health, headquarters will be in Montgomery.—James G. McAlpine, Ph.D., Montgomery, has resigned as director of the state health department laboratories to return to his former home in Connecticut, it is reported.

CALIFORNIA

Venereal Disease Control Center—An appropriation of \$32,244 has been made available through the social security act to establish a venereal disease control center in southern California under the direction of Dr. George Parrish, health officer of Los Angeles. The program includes the employment of thirty-six persons as nurses, social workers and laboratory technicians.

Five Year Program of Graduate Education—The California Medical Association has prepared a program of graduate education to be delivered throughout the state over a five year period. The conferences will be clinical and not didactic. The University of California, Stanford University, University of Southern California and the College of Medical Evangelists will cooperate with the state medical association by making available members of the faculties as instructors for these conferences. The California Tuberculosis Association, the California Heart Association and the Los Angeles County Clinical Statistical Association on request, will recommend members of their organizations suitable for teaching tuberculosis and heart disease. In addition to the specialties, the courses will cover abdominal disease, diseases of metabolism, genito-urinary and venereal infections, diseases of the central nervous system, laboratory equipment and technic drugs vaccines and serums.

CONNECTICUT

Personal—Dr. Delmar Allan Craig has resigned as head of the Charlotte Hungerford Hospital Torrington to accept a similar position at the Eastern Maine General Hospital, Bangor, according to the *New England Journal of Medicine*.

Hospital and Medical Society Receive Bequest—The Hartford Medical Society will receive the professional library and instruments of the late Dr. Edward K. Root, Hartford, who died August 12. The will also contains a bequest of \$2,000 for the Hartford Hospital, to be known as the Edward K. Root Fund, the income from which is to be used for providing medical periodicals for the house staff of the hospital.

Society News—Dr. Cornille Heymans, professor of pharmacology and therapeutics, University of Ghent, Belgium, discussed 'Blood Pressure Regulation and Experimental Hyper-

tension" before the Yale Medical Society, New Haven, November 15. At a joint meeting of the society with the atypical growth study unit, November 10, Dr William E Gye, director, Imperial Cancer Research Foundation of London, spoke on "Tumors Transmissible with Viruses"

FLORIDA

New Officers of State Board—Dr Julius C Davis, Quincy, was recently elected president of the state board of medical examiners and Dr Harold D Van Schaick, Jacksonville, vice president

Society News—Dr Herbert L Bryans, Pensacola, was elected president of the Gulf Coast Clinical Society at its annual session in Biloxi, Miss., November 4. Pensacola was designated as the place of the next meeting. Dr Jacques H Baumhauer, Mobile, Ala., is secretary-treasurer

IDAHO

Society News—At a meeting of the Pocatello Medical Society, November 4, Dr Casper W Pond, Pocatello, spoke on "Blood Dyscrasias in Relation to Infections and Hemorrhage"

New Tuberculosis Hospital—Lava Hot Springs in Bannock County has been selected as the site for a new \$208,000 state tuberculosis hospital, according to *Northwest Medicine*. Construction must be started by December 15, according to terms of the federal grant, which amounts to 45 per cent of the total cost

ILLINOIS

Personal—Dr Arthur E Lord, Plano, surgeon general, Illinois National Guard, was guest of honor at a dinner in Chicago, November 17, marking his election as president of the Association of Military Surgeons of the United States

Change in Typhoid Quarantine Regulations—The state department of health announces a change in the quarantine regulations concerning typhoid, requiring all members of a household in which there is a typhoid patient to submit two specimens for laboratory examination before they are released from quarantine. Heretofore unaffected persons on the premises who were immunized against typhoid were excused from quarantine. The purpose of the change is to facilitate the detection of carriers, it was stated. Up to November 10, 536 cases of typhoid had occurred in Illinois and twenty-two carriers had been identified

State Public Health Conference—The annual state conference on public health will be held in Springfield, December 9-10, under the auspices of the state department of public health. The speakers will include

Dr Philip C Jeans, Iowa City, Nutritional Deficiency in Public Health
Herbert F Moore, Sc D, Urbana, Social Engineering in the Health Field

Dr Frederick T Lord, Boston, Lobar Pneumonia and Serum Therapy

Dr Julius Levy, Newark, N J, Preventive Mental Hygiene

Dr Irving S Cutter, Chicago, Education in Preventive Medicine

Dr Don W Gudakunst, Detroit, Newer Trends in School Health Practice

Dr Charles F McKhann, Boston, Preventing Hospital Infections

Dr David C Elliott, Hagerstown, Md, A Venereal Disease Program

Dr Paul H Harmen, Springfield, Epidemiology of Polymyositis

Dr Guy Howard Gowen, Springfield, Trailer Laboratory in Typhoid Control

Chicago

Branch Society Meetings—Dr Walter C Alvarez Rochester, Minn., will address a joint meeting of the Englewood and Stock Yard branches of the Chicago Medical Society, December 7, his subject will be "The Care of the Aged". At a meeting of the Evanston branch, December 2, the speakers included Dr Budd C Corbus on "A Serological Control of Neisserian Infections with the Bouillon Filtrate". Dr Russell M Wilder, Rochester, Minn., discussed "Pathogenesis and Etiology of Diabetes" at a meeting of the North Side branch, December 2. Drs William H Browne and Julius H Hess will present the scientific program before the North Shore branch, December 7, their subjects are "Prevention and Management of Premature Labor," and "Care of Premature Labor," respectively

IOWA

Personal—Dr Harry P Lee has resigned as professor of genito-urinary surgery at the State University of Iowa College of Medicine, Iowa City, to enter a medical school in Spokane, Wash.—Dr Anton R Schier, medical superintendent of the State Hospital at Woodward, School for Feeble-minded at Woodward

Refresher Courses—The speakers' bureau of the Iowa State Medical Society began its third series of refresher courses this fall at Osage and Nevada, November 1. Two lectures are given at each meeting, one on obstetrics and one on pediatrics, over a period of five weeks. Cooperating are the State University of Iowa College of Medicine, the Iowa Pediatric Club, the Central Association of Obstetricians and Gynecologists and the state department of health. Lecturers include Drs Roy I Theisen, Dubuque, Philip C Jeans, William F Menert, Everett D Plass and John H Randall, all of Iowa City; Glenn E Harrison, Mason City; John M Havek, James E Dyson and Lester D Powell, Des Moines, and Cecil W Seibert, Waterloo

KANSAS

Personal—Dr Charles B Stephens, Iola, has been appointed health officer of Topeka. Dr Stephens was health officer of Allen County for several years and has been secretary of the Allen County Medical Society since 1933

"Cancer Specialist" Cooper Enjoined—W W Cooper, self-styled cancer specialist of Altoona, has appealed to the Supreme Court of Kansas from a recent decision of a district court enjoining him from practicing the healing art in Kansas. Cooper had undertaken to treat cancer, using a zinc chloride paste. His counsel is E M Perdue, who is both a physician and a lawyer and who, according to information in the files of the *American Medical Association*, appeared in 1932 as a witness for Norman Baker of Muscatine, Iowa, in his unsuccessful suit against the Association

Society News—The Sedgwick County Medical Society was addressed by Dr Ernest M Seydell, Wichita, November 16, on "Treatment of Septicemia—A Modern Conception". Dr John W Duncan, Omaha, discussed "Surgical and Hormone Treatment of Undescended Testicle" before the Wyandotte County Medical Society, Kansas City, November 2. At a joint meeting of the medical societies of Marion, McPherson and Harvey counties in Marion, October 27, Drs Karl A Menninger and Norman Reider, Topeka, discussed "The Psychoneurotic and the General Practitioner" and "Headaches" respectively

MICHIGAN

Personal—Dr Isaac N LaVictoire, assistant physician at the Kalamazoo State Hospital, has been appointed psychiatrist for the Hospital of the State House of Correction and branch prison at Marquette and the Michigan State Reformatory at Ionia, it is reported. He will be succeeded at Kalamazoo by Dr Charles O Holder

Free Drugs for Venereal Diseases—The Michigan State Department of Health announced that free distribution of drugs in the campaign against venereal diseases was to begin December 1. Newspapers reported November 12. About \$50,000 annually is available to finance this work incident to the campaign and distribution centers for the drugs will be located in the health departments of Detroit, Lansing, Grand Rapids, Flint, Saginaw, Pontiac, Jackson, Kalamazoo, Battle Creek and Marquette

New Laboratory for State Health Department—The new \$250,000 laboratory of the state department of health on the DeWitt Road, just northwest of Lansing was dedicated November 12. Dr Frederick G Novy, dean emeritus of the University of Michigan Medical School, Ann Arbor, and professor emeritus of bacteriology, gave the address at a banquet at the Hotel Olds, under the auspices of the Michigan branch of the Society of American Bacteriologists and directors of registered laboratories. Dr Novy assisted in establishing the state's first public health laboratory in 1887. The dedication of the new laboratory also served to commemorate the fifty years of public health laboratory service in Michigan. The new three story building was financed in part by federal funds and provides laboratory facilities for the department of agriculture and the state board of pharmacy as well as for the diagnostic and research control laboratories of the state department of health

Society News—At the annual meeting of the Michigan Association of Industrial Physicians and Surgeons in Detroit, October 12, Dr Earl I Carr, Lansing, was elected president. Dr Francis T McCormick, Detroit, vice president and Dr Donald F Kudner, Jackson, secretary. Dr William G Gamble Jr, Bay City, addressed a joint meeting of the Menominee and Marinette medical societies, October 25, on syphilis. At a meeting of the Ingham County Medical Society, October 19, the creation of a county health unit was unanimously approved. Dr George T Antlen Jr, Grand Rapids, addressed the Wexford County Medical Society in Cadillac

November 11, on "Basic Principles of Fractures"—Dr Walterman Walters, Rochester, Minn., discussed "Developments in Surgery of the Stomach and Duodenum" before the Kalamazoo Academy of Medicine November 16—Dr Charles E. Pope, Evanston, Ill., addressed the Muskegon County Medical Society in Muskegon, November 19, on "Cancer of the Rectum"

MINNESOTA

Society News—At a meeting of the Park Region Medical Society in Fergus Falls, October 13, Dr Martin Nordland, Minneapolis, discussed gonorrhea—The Wabasha County Medical Society was addressed at Kellogg, October 7, by Dr Hugh R. Butt, Rochester, on "Medical Treatment of Diseases of the Gallbladder"—Among others, Dr Magnus C. Petersen, Willmar, discussed "Cisternal Punctures with Special Reference to the Aged" before the Minnesota State Medical Officers Association in Willmar, October 26

NEW YORK

Health Department Widens Pneumonia Serum Distribution—With increased funds provided by the 1937 legislature the state health department will have available to physicians sufficient antipneumococcus serum of types I and II to meet an anticipated increase in demand and in addition will distribute serums of types V, VII and VIII. Initial shipments of the latter three types have been sent to twenty-four district laboratories

Advisory Board on Narcotic Control—An advisory board to assist the new bureau of narcotic control in the state department of health has been appointed by the state health commissioner, Dr Edward S. Godfrey Jr. The members represent the state medical, dental, veterinary and pharmaceutical associations and the drug manufacturing industry. They are Dr Homer L. Nelms, Albany, Harvey J. Burkhart, DDS, Rochester, L. L. Parker, DVM, Catskill, Nicholas Gesoalde, Brooklyn, pharmacist, and Carl M. Anderson, New York, representative of the Drug, Chemical and Allied Trades section of the New York Board of Trade

New York City

Restrict Sale of Sulfanilamide—The New York City Board of Health has prohibited the sale of sulfanilamide throughout the city except on prescription of a physician, according to *New York Medical Week*

Hospital Lectures—The Bronx Hospital began a series of afternoon lectures for physicians November 9 with an address by Dr Alan L. Barach on "Peripheral Circulatory Failure and Acute Pulmonary Edema Occurring as Complications in Pneumonia." Dr Elliott P. Joslin, Boston, will give the second December 7 on "Diabetes Mellitus," and Dr Russell L. Cecil the third December 21 on "Chronic Arthritis"

District Meeting—The Second District Branch of the Medical Society of the State of New York held its annual meeting at Garden City November 17. The program was on cancer and renal pathology with exhibits and clinical lectures on both subjects. The speakers were Drs Norman Treves, New York, Algernon S. Warinner and Gladys Carr, Hempstead, L. I., on cancer, Tasker Howard, Howard T. Langworthy and Theodore J. Curphey, all of Brooklyn and Francis Riley, Jamaica, on renal pathology

Francis P. Garvan Dies—Francis P. Garvan, president of the Chemical Foundation Inc., died November 7 of pneumonia at his home, aged 62. Mr. Garvan, a lawyer, was known for his efforts to stimulate interest in chemistry, particularly as applied to medicine. Through the foundation he provided large sums for cancer investigation at Johns Hopkins Hospital and since 1930 has contributed to the support of the *American Journal of Cancer*. In 1928 he established a fund of \$195,000 known as the John J. Abel Fund for Research on the Common Cold, also at Johns Hopkins. An important publication of the foundation some years ago was "Chemistry in Medicine," to which forty-three scientists contributed articles on various fields under the editorship of the late Prof. Julius Steglitz, Chicago. Mr. Garvan was born in Connecticut and graduated from Yale University in 1897 and from New York University Law School in 1899. During the World War he became chief of the U. S. Bureau of Investigation in New York and later was United States Alien Property Custodian. From 1919 to 1923 he was dean of the Fordham University Law School. He was the only layman ever to receive the Priestley Medal of the American Chemical Society, which was conferred on him in 1929. The American Institute of Chemists also honored him with a medal and he had received honorary degrees from Fordham, Yale, Trinity and Notre Dame universities.

NORTH CAROLINA

Personal—Dr Charles D. Thomas of the staff of the North Carolina Sanatorium for the Treatment of Tuberculosis Sanatorium, has been appointed assistant superintendent and associate medical director, succeeding Dr Samuel M. Bittinger, who has been made assistant superintendent and medical director of the new sanatorium at Black Mountain.

OHIO

Personal—Dr Leo F. Hall, Cleveland, deputy commissioner of Cuyahoga County, has been appointed commissioner. Dr James A. Doull has been acting commissioner since the expiration of the term of Dr Robert Lockhart.

University News—The Commonwealth Fund of New York has made a grant of \$10,857 annually for three years to the Western Reserve University School of Medicine, Cleveland, for the research of Dr Joseph M. Hayman, associate professor of medicine, on chronic nephritis.

Society News—Dr James V. Seids, Cleveland, addressed the Huron County Medical Society, Willard, November 10, on "Treatment of Gallbladder Disease and Its Complications"—Dr Herbert L. Brumbaugh, Dayton, addressed the Warren County Medical Society, Lebanon, November 2, on "Treatment of Fractures of the Hip"—Dr Fred Wise, New York, addressed the Academy of Medicine of Cincinnati, November 16, on "Further Experiences with Mapharsen: Its Use in Latent Syphilis"—James R. Blayney, DDS, Chicago, addressed the annual joint meeting of the Toledo Academy of Medicine and the Toledo Dental Society, November 5, on "Present Day Evaluation of a Pulpless Tooth"

PENNSYLVANIA

Society News—Dr Joseph Earle Moore, Baltimore, addressed the Cambria County Medical Society, Johnstown, November 11, on "Syphilis: Diagnosis and Treatment"—Dr Joseph A. Perrone, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, November 4, on "Bronchoscopy as an Aid in the Diagnosis and Treatment of Pulmonary Conditions"

Secretary Donaldson Honored—At the annual meeting of the Medical Society of the State of Pennsylvania in Philadelphia in October the past presidents and the board of trustees of the society presented to Dr Walter F. Donaldson, Pittsburgh, secretary of the society for nineteen years, an oil portrait of himself. Dr Arthur C. Morgan, Philadelphia, made the presentation speech.

Memorials at Reading Hospital—Three memorials to persons prominent in the development of Reading Hospital, were unveiled at the annual staff banquet November 3. Tablets were erected to Dr Charles H. Hunter, one of the founders of the hospital, who died in 1870, and to Dr Charles G. Loose, for fifty-three years a member of the staff, who died in 1935. The third memorial was a bronze head of Mr. Gustav Oberlaender, for many years president of the board of directors. Dr William Gerry Morgan, Washington, D. C., who was an intern at the hospital in 1893, gave the address at the ceremony.

Philadelphia

Hospital News—Mount Sinai Hospital began its sixth series of health talks for the public with a lecture November 17 by Dr Frank E. Levy, entitled "Has Diabetes Been Conquered?"

Cancer Forum—The women's auxiliary of the Lankenau Hospital Research Institute presented a cancer forum November 29-30 at the Bellevue-Stratford under the direction of Mrs. Alfred M. Gray and Dr. Stanley P. Reimann, research director of the institute. Among the speakers were:

- Dr. Burton T. Simpson: Buffalo Activities of New York State in the Control of Cancer
- Dr. Madge T. Macklin: London Ont. The Vexations and Compensations of Trying to Study Human Heredity Especially in Cancer
- Dr. Ludwig Hektoen: Chicago and Washington D. C. The Federal Government in Cancer
- Dr. Logan Clendening: Kansas City Mo. Some Issues at Stake in the Cancer Problem
- Dr. Foster Kennedy: New York Psychological Attitudes Toward Cancer
- Oscar Riddle, Ph.D.: Cold Spring Harbor N. Y. Educational Aspects and Luminous Research

Various organizations were represented among the sponsors of the forum.

Society News—The Philadelphia County Medical Society marked the one hundred and fiftieth anniversary of the signing of the Constitution at its meeting November 22 with the following program: Roland S. Morris, president of the American Philosophical Society, "The Birth of the Constitution and the American Philosophical Society"; Dr. George P. Muller

"Early History of the College of Physicians", Dr William Pepper, "Early Philadelphia Medicine and the University of Pennsylvania," and Dr William Egbert Robertson, "Dr Rush and the Signers of the Constitution"—Among speakers at a meeting of the Physiological Society of Philadelphia, November 15, were Ben King Harned, Ph D., and Versa V Cole, on "Hyperglycemia Produced by a Synergetic Action of Strychnine and Physostigmine", Drs Ernest A Spiegel and John B Price, "Conduction of Labyrinthine Impulses to the Cerebral Cortex."

TEXAS

Advisory Board for Crippled Children—Drs William B Carrell, Dallas, and Edwin G Schwarz, Fort Worth and Mr Robert Jolly, superintendent of the Baptist Hospital, Houston, have been appointed to a board to advise the crippled children's division of the state department of education, it is reported.

Personal—Dr William L Baugh, Lubbock, was appointed a member of the state board of health November 2, to succeed the late Dr Silas J Alexander, Hearne—Dr Frances T Vanzant Houston, will go to Spain to join an American medical relief unit, it is reported—Dr and Mrs Charles E Mays, San Angelo, recently celebrated their golden wedding anniversary, according to the *Texas State Journal of Medicine*—Dr Wilfred J Allison, recently of Baltimore, has been appointed medical director of the Southwestern Life Insurance Company with headquarters in Dallas, it is reported.

District Meetings—The annual meeting of the Fourth District Medical Society was held in Coleman October 19-20. Among the speakers were Drs Thomas H Cheavens, Dallas, "Use and Misuse of Sedatives and Hypnotics", George R Enloe, Fort Worth, "Acute Infections of the Hand", Rudolph K Harlan, Temple, "The Tachycardias" and William E Schulkey, San Angelo, "Trend of Traumatic Surgery"—At a meeting of the Eleventh District Medical Society in Jacksonville, October 13, the speakers included Drs Reuben B Anderson Jr, Fort Worth, assistant secretary of the Texas State Medical Association, on "Activities of the State Medical Association", Leroy Trice, Palestine, "Surgical Treatment of Nephroptosis," and Percy M Girard, Dallas, "Treatment of Recent Cases of Acute Poliomyelitis."

WASHINGTON

Society News—Among speakers who addressed the Spokane County Medical Society, Spokane, November 18, were Drs Asa E Seeds, on "X-Ray Irradiation in Cervical Adenitis in Children", Jean D Kindschi, "Congenital Malformations of the Uterus," and George Clifford Smith, "Intravenous Medication"—A program on pneumonia will be presented at the meeting of the King County Medical Society, Seattle, December 6, by Drs Harry J Friedman, Theodore W Houk and Donald G Evans.

County Society in New Offices—The King County Medical Society has recently opened new executive offices in the Cobb Building, Seattle, with Miss Ernestine C Appy as executive secretary. The new quarters consist of the society's library, a reception room, the secretary's office an ediphone room and a committee room. The ediphone room is arranged so that members may record notes on their reading and take the wax records to their own offices for transcription, or if they do not have reproducing machines their secretaries may use the equipment at the library.

WISCONSIN

In Memory of Dr Gaenslen—The Milwaukee school board recently announced that a new orthopedic school now under construction will be named the Frederick J Gaenslen School for Crippled Children in honor of the late Dr Gaenslen for many years orthopedic surgeon to the Columbia and Milwaukee hospitals and consulting orthopedic surgeon to the Milwaukee Children's Hospital. Dr Gaenslen who died March 14, was a member of the Council on Physical Therapy of the American Medical Association from 1931 to 1934.

Society News—Drs Geza de Takats Chas. and Frances J Kinsella, Minneapolis, addressed the La Crosse Medical Society, La Crosse, October 12 on "Finger Accidents" and "The Application of Sincalculous Pulmonary Disease" respectively.—Dr Hardgrove, Milwaukee, addressed the Winnebago Medical Society October 21 on "Convalescence and"—Dr Reed M Nesbit Ann Arbor M

"Transurethral Prostatectomy Indications for and the Limitations of Operation" The motion picture on syphilis produced by the American Medical Association and the U S Public Health Service was shown at this meeting—Dr Elmer L Sevringhaus, Madison, addressed the Milwaukee Academy of Medicine November 16 on "Endocrine Therapy in General Practice."

ALASKA

Research Laboratory in the Arctic—Dr Victor E Levine, professor of biological chemistry and nutrition and head of the department, Creighton University School of Medicine, Omaha, has established a medical and biological laboratory in the arctic at Point Barrow as a cooperative research project of the U S Public Health Service and Creighton University. Dr Levine with an assistant, Delbert F Foord of the University of California, arrived in Alaska in August and expects to remain for a year. The laboratory equipment includes x-ray apparatus, a basal metabolism machine, a biophotometer for determining vitamin A deficiency, an apparatus for estimating civitamic acid in the blood, an instrument for measuring capillary fragility, biologic stains, bacteriologic mediums and reagents for blood and urine chemistry.

GENERAL

Society News—Dr Charles S Holbrook, New Orleans was chosen president-elect of the Southern Psychiatric Association at its annual meeting in San Antonio, Texas, in October, and Dr George P Sprague, Lexington, Ky, was installed as president. The next meeting will be in Atlanta.

Academy of Dermatology and Syphilology to Be Organized—At a meeting in Detroit January 14-15 at which the Detroit Dermatological Society will be host to the Central States Dermatological Society, the Dermatological Conference of the Mississippi Valley and other local organizations, it is proposed to organize an Academy of Dermatology and Syphilology. All full time practitioners and teachers of dermatology and syphilology in the United States and Canada have been invited to attend. Early plans for the organization were reported in THE JOURNAL, October 9, page 1208.

Golfers' Special to San Francisco—A "golfers' special" is being arranged for persons attending the annual session of the American Medical Association in San Francisco, June 13-17. The trip includes sightseeing, entertainment, six games of golf en route, and a day in Hollywood. The cities to be visited include New Orleans, Houston, Galveston, San Antonio, Los Angeles, Del Monte, San Francisco, Portland, Seattle, Vancouver, Lake Louise and Banff will be visited on the way back. Nongolfers as well as golfers and their ladies are invited. Additional information may be obtained from Dr Walt P Conaway, president, American Medical Golfing Association, 1723 Pacific Avenue Atlantic City, N J.

New Annual Prize—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces a new annual prize of \$500 for a thesis to be presented at the annual meeting of the association. Those eligible include (1) interns, residents or graduate students in obstetrics, gynecology and abdominal surgery and (2) physicians who are actually practicing or teaching those subjects. Competing manuscripts must be presented in triplicate under a nom de plume before June 1 to the secretary, Dr James R Bloss, 418 Eleventh Street, Huntington, W Va. They must be limited to 5000 words with such illustrations as are necessary for a clear exposition of the thesis and must be typewritten (double spaced) on one side of the paper, with ample margins. The paper must be presented at the next annual meeting (September) of the association, without expense to the association and in conformity with its regulations.

Junior Chamber of Commerce to Cooperate in Venereal Disease Campaign—Dr Roy L Smith, Tulsa, Okla., has been appointed chairman of a National Health Committee organized by the United States Junior Chamber of Commerce at its recent annual convention to cooperate with the U S Public Health Service and with state and local medical societies in the current campaign against venereal disease. Dr Smith is organizing committees in every state under the chairmanship of physicians, when they are available, dentists or qualified laymen. Twenty-two states have been organized so far. The committee plans to carry on an intensive campaign, with its own organization in order to acquaint young business and professional men with the venereal disease problem to cooperate with medical societies and health departments in arranging programs and to campaign for legislation and appropriations to deal with the diseases.

Dr Mosher Receives Academy Award—Dr Harris P Mosher, Walter Augustus LeCompte professor of otology and professor of laryngology, Harvard University Medical School and the graduate school, Boston, was presented with the gold Medal of Honor of the American Academy of Ophthalmology and Otolaryngology at its annual convention in Chicago October 13 for distinguished service in the field of otolaryngology and for fostering graduate education in this specialty. The medal was presented at the annual banquet of the academy, at which Dr Mosher as guest of honor delivered the principal address. A native of Maine, Dr Mosher graduated from Harvard in 1896. He was chairman of the Section on Laryngology, Otology, and Rhinology of the American Medical Association in 1933 and president of the American Academy of Ophthalmology and Otolaryngology in 1928, he was installed as president of the American Otolological Society in June of this year and has served for many years as president of the American Board of Otolaryngology.

Medical Bills in Congress—The Secretary of Agriculture has in compliance with S Res 194 and H Res 352, submitted a report to the Senate and to the House on deaths due to Elixir of Sulfanilamide-Massengill. To protect the public from drugs which are dangerous because of their inherent toxicity, the Department of Agriculture, in its report, recommended that legislation be enacted to provide at least the following: (1) License control of new drugs to insure that they will not be generally distributed until experimental and clinical tests have shown them to be safe for use, (2) prohibition of drugs which are dangerous to health when administered in accordance with the manufacturer's directions for use, (3) requirement that drug labels bear appropriate directions for use and warnings against probable misuse, and (4) prohibition of secret remedies by requiring that labels disclose fully the composition of drugs. These recommendations, the report states, are limited to provisions which the department believes should be enacted to safeguard the public from the dangers of drugs of one type. That type includes the inherently toxic drugs, such as elixir of sulfanilamide, dinitrophenol and cinchophen. *Bills Introduced*—H R 8453, introduced (by request) by Representative May, Kentucky, proposes to provide for a commissioned strength of 14,659 for the regular army and specifies that "the proportional increases as computed under this Act for the Medical Administrative Corps and Veterinary Corps shall be assigned to the Dental Corps." H R 8474, introduced by Representative Dixon, Ohio provides that in the administration of laws conferring benefits on veterans of the World War women citizens of the United States who served overseas with the War Department during the World War, as members of "The Army Women's Overseas Unit" shall be held and considered to have enlisted, enrolled or drafted into active service in the military forces of the United States.

CANADA

Society News—Dr Byron P Stookey, New York, addressed the Academy of Medicine of Toronto, November 2, on "The Treatment and Management of Vertebral Fracture Dislocations in Association with Spinal Cord Injuries."—Dr George S Young, Toronto, was elected president of the Royal College of Physicians and Surgeons of Canada at its annual meeting in Ottawa, October 31.

LATIN AMERICA

Sight Conservation Institute in Cuba—Announcement is made of the formation of the "Instituto Protector de la Vista" in Havana with Dr Tomas R Yanes as president and with leaders in various fields concerned with the problem as members of its directing council. The institute plans to make statistical studies of the causes of diseases of the eye and to carry out an educational campaign concerning them.

FOREIGN

Society News—The fourth International Congress of Comparative Pathology will be held in Rome in 1939. Subjects so far proposed for discussion are virus diseases, heredity in pathology, immunity in protozoan diseases and some topic in the field of phytopathology.

Eastman Dental Clinic in Paris—The Eastman Institute of Dentistry and Stomatology in Paris, a benefaction of the late George Eastman Rochester, N Y, was opened October 21. This is the fifth dental clinic for children erected in Europe with funds provided by Mr Eastman the others being in London, Rome, Brussels and Stockholm. Harvey I Burkhardt DDS Rochester, presented the institute to the city of Paris as a representative of the Eastman interests. Dr Burkhardt laid the cornerstone of the building July 29 1935.

Congress for Experimental Cytology—The fifth International Congress for Experimental Cytology will be held in Zurich August 7-12, 1938, immediately before the International Physiological Congress. The sessions will be devoted to symposiums on the following subjects: epithelium in cultures and in the organism, structure of chromosomes, mechanism of mitosis, cancer cells and normal cells, experimental cytology and the study of viruses, ultrastructure of protoplasm and its products and chemistry of the cell. Those wishing to take part in the program should submit their papers (with a summary not exceeding 200 words) to Prof W von Mollendorff, 9 Plattenstrasse, Zurich, Switzerland, before April 15, 1938. Information may be obtained from Professor von Mollendorff or from Dr Harald J C Okkels, Institute for Pathological Anatomy, University of Copenhagen.

CORRECTION

Carcinoma Instead of Sarcoma—In a New York City news item in THE JOURNAL, November 6, reporting a meeting of the New York Pathological Society on October 28, the title of a paper by Drs Andrea Saccone and Abraham Rosenthal was given as "Colostrum Cell Sarcoma of the Breast." This should have been "Colostrum Cell Carcinoma of the Breast."

Government Services

Physicians Wanted for Civilian Conservation Corps

The Medford, Ore, district of the Civilian Conservation Corps has several openings for physicians at a salary of \$225 a month, the district adjutant reports. Those interested should send their qualifications to the District Surgeon, Medford CCC District, Medford, Ore.

Consultant in Development of Orthopedic Services

Dr John C Wilson, clinical professor of orthopedic surgery, University of Southern California Medical School, Los Angeles, has been appointed consulting orthopedist on the staff of the Crippled Children's Division of the Children's Bureau, U S Department of Labor. He will serve as consultant for the Western states in the development of services for crippled children under the social security act. The law authorizes an annual appropriation of \$2,850,000 to be administered by the Children's Bureau for extending and improving services for crippled children in rural areas and areas of severe economic distress. Forty-five states, Alaska, Hawaii and the District of Columbia are now receiving federal grants for this work. Dr Wilson graduated from the University of California Medical School, San Francisco, in 1912. He enlisted with the medical corps of the U S Army in 1917 and at the time of his discharge in 1919 was chief orthopedic surgeon of General Hospital number 6 in Atlanta, Ga. He is president-elect of the American Academy of Orthopedic Surgery.

Positions with the Children's Bureau

The U S Civil Service Commission announces open competitive examinations for the following positions with the Children's Bureau, U S Department of Labor: principal specialist in maternal and child health at a salary of \$5,600 a year; senior specialist in maternal and child health, \$4,600; specialist in maternal and child health, \$3,800; and associate in maternal and child health, \$3,200. Employment lists will be established for the following branches: pediatrics, obstetrics, orthopedics, general practice (maternal and child health) and psychiatry for children. The positions will include both administration and research. Candidates will not be required to report for examination at any place but will be rated on the extent and quality of their education and experience. Details of the qualifications may be obtained from the Secretary, Board of Civil Service Examiners, at any first class postoffice, from the Civil Service Commission at Washington or from the district office in any of the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St Louis, St Paul, San Francisco, Honolulu, Balboa Heights, C Z and San Juan, P R. Applications must be on file with the commission at Washington not later than December 28 if received from states other than the following for which the date is December 31: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming.

Juvenile Extension of National Health Insurance

The minister of health has introduced in the House of Commons the national health insurance (juvenile contributors and young persons) bill. This provides medical benefit for boys and girls who on leaving school become employed before reaching the age of 16, at which age national health insurance benefit previously began. The bill will thus bridge the gap in medical supervision which now exists between the school medical service and the beginning of insurance. It is calculated that 1,000,000 boys and girls will come under the scheme. The cost of medical benefit and its administration for these juveniles will be defrayed, like existing health insurance, as to six sevenths in the case of boys and four fifths in the case of girls out of the contributions of the juveniles and their employers, and as to the remainder by the government. It is estimated that the total amount required to cover the cost of medical benefit, including the capitation fee to panel physicians of \$2 a year, the supply of medicines and administrative expenses of insurance committees, will be \$3 a head per annum.

Medical School in London for Women

For many years London has had twelve undergraduate medical schools. The establishment of another is a new event for the present generation. The West London Hospital, which has for forty years been a postgraduate school, is now to become a full medical school. The opportunity has been provided by the deficient accommodation in London for the clinical teaching of woman students. There is only one medical school (300 beds) devoted to the medical education of women, and most of the schools do not admit them or take them only in a limited number. It is not proposed that the West London Hospital shall confine its school to women but that, unlike the other medical schools, students shall be taken regardless of sex. The dean, Dr M. E. Shaw, states that the proportion of students to beds will not exceed one to three, which is the recognized optimum. As the number of beds in the hospital is 239 it will take some years for the school to fill. It is not proposed to abandon the postgraduate teaching which the school has successfully carried on for many years and in which it has been a pioneer. This new medical school marks an advance in the movement for the medical education of women which has had to fight a long battle against prejudice. The Senate of the University has for some time been troubled with the inadequate provision in London for the clinical training of women. One of its members, the dermatologist Sir Edward Graham Little, states in a letter to the *Times* that twenty women who had pursued their preclinical studies in the schools of the university were unable to secure entrance for the clinical course at any London school. The recognition by the government of the West London Hospital as an "external" school of the university, which is no doubt preparatory to its becoming a constituent school when it can be shown that its financial position is satisfactory, will go a long way to solve the problem.

International Peace Campaign

The first conference of the International Peace Campaign was held at University College, London. A discussion took place on the duty and right of physician to take an independent and critical attitude to all questions of war and war preparations. The manner in which the profession was now committed to cooperate in air raid precautions without having had them examined and without impartial scientific efficacy was deplored. War was compared to its prevention was as much the duty of the physician.

prevention of other causes of suffering and death. Two physicians described a similar movement in the Netherlands. The following resolution was carried unanimously: "That the medical profession has the duty and right to assume an independent and critical attitude in regard to government policy affecting war and war preparations." The practical steps to be taken by physicians in all countries were discussed. It was thought that more discussion on international affairs as they affected physicians might take place in the branches of the British Medical Association. The resolution passed at the annual meeting of the British Medical Association, held this year at Belfast, initiating an inquiry into the psychological causes of war was considered a great advance. The value of international medical congresses in obtaining cooperation and understanding was stressed.

The Treatment of Intestinal Strangulation

At the Research Laboratories of the Royal College of Surgeons, Mr G. C. Knight has done important work on intestinal strangulation. It has been previously suggested that the toxic depressor substances found in the urine of human patients with known strangulation are similar to those demonstrated in the intestine, peritoneal fluid and blood of animals in which strangulation has been experimentally produced. To test this, blood and peritoneal fluid from human patients were injected intravenously into the cat. It was found that depressor substances appear in the peritoneal fluid within two hours of the onset of strangulation and then increase as the viability of the intestine deteriorates and that similar substances are present in the venous blood of the strangulated loop and therefore are liable to be returned to the circulation on release of the strangulation. The fact that release of a viable segment of intestine does not always result in improvement of the condition of the experimental animal has been previously shown. To determine the factors responsible for the death of the animal, which occasionally occurs under these circumstances, a series of experiments were performed with the following results. In 15 per cent of cases, release of a moderate viable strangulation was followed by death, but only when the animal's general condition had been impaired by toxic absorption prior to the release. In 80 per cent there was evidence of the return of toxic substances to the general circulation, as shown by profound cardiac effects or lowering of blood pressure. When the circulation was in good condition prior to the release, recovery occurred.

The moral for the treatment of a toxic human patient is as follows: 1. It is advisable to remove as much peritoneal fluid as possible without prolonging the operation and handling unduly. 2. Exteriorization or resection of doubtful intestine is safer than return or invagination, owing to the possibility of further absorption.

Experiments were also made to assay the degree to which surgical shock modifies the clinical picture in experimental long loop strangulation—corresponding clinically to mesenteric thrombosis. The rapidly fatal outcome of these cases could not be accounted for solely by absorption of toxic substances which were demonstrated in small amounts in the peritoneal and lymphatic fluids. Fluid loss as a cause of death was also excluded. By oscillographic experiments it was shown that after producing such a lesion there is a great increase in the nerve impulses at the splanchnic area. Death therefore appears to be due, in part at least, to shock, and therefore these cases form a different category from the more usual smaller strangulations.

Gas Masks for Babies

The danger of another great war is never far from the thoughts of Europeans. In this country we hope for the best but prepare for the worst. Thirty million gas masks for civilians are being provided. The problem of masks for babies is offered some difficulty, but government experts are endeavoring to find a standard size in sight of solution. Material must allow for a certain amount of flexibility and it is therefore

that it will not be long before gas masks for infants and children will be economically produced. Government officials have carried out fitting trials at Dr Barnardo's Homes for Children to determine the range of sizes required for respirators in the case of children under school age. There was no difficulty in trying on the masks. The children showed no sign of crying and scampered about after being fitted with respirators. It is expected that as a result of the trials useful evidence will be forthcoming on two points: (1) the earliest age at which a child may be expected to be able to use a respirator, (2) the necessity or otherwise of extra small sizes of respirators in addition to the stock sizes now being manufactured.

Electrical Hearing Aids in a School for the Deaf

Lord Horder inaugurated a special sound installation at the cinema of the Royal School for Deaf and Dumb Children, Margate. Experiments in the use of electrical hearing aids have been carried out during the past three years at the school, which is now the first to be equipped with apparatus that enables a fair proportion of its pupils to distinguish the sounds reproduced in a talking film. A record is made, by means of tests on an audiometer, of the exact amount of hearing loss of each child. It has been found that those who do not have a greater hearing loss than 70 per cent can derive benefit from hearing aids. The sound reproduced with the film is put on to a line through a special device which ensures that it shall not exceed a certain level of volume. The line goes to sockets fixed on the back of each chair, and each child has a small box from which a lead is plugged into the socket. The special 'unmasked hearing' headphones which the child uses ensure that the speech sounds are clearly defined, so that the consonants in particular are easily distinguished. The system of 'unmasked hearing' is regarded as the most important feature of the installation because its use helps in a progressive appreciation of speech sounds.

Lord Horder said that the school made a double appeal to the physician—as a humanitarian and as a scientist. These hearing aids achieved what was a valuable addition to the physical and mental well being of the children of the school.

The Heritability of Rheumatic Diseases and Goiter

Claussen of Frankfurt-on-the-Main recently discussed the heritability of rheumatic disease before the Medical Society of his city. According to the pathergy theory of Roessle and Klinge, rheumatism is a disease of the entire organism, a specific hyperergic reaction which, under other supervening influences, may lead to various types of illness. Genetic research has been able to supplement this important hypothesis by examination of the hereditary constitutional tendency to hyperergic reaction. In a vast majority of cases of articular rheumatism the sensitization comes from tonsillitis, usually of a chronic form. Claussen observed this interrelation in 70 per cent of 234 students affected with mild ailments. Other observers report the same syndrome in 50 per cent of all cases of rheumatism among soldiers on active service. The pathogenesis of tonsillitis is favored by a susceptibility to catarrh which, according to research on twins, appears to be heritable. If the organism once becomes hyperergic sensitizing factors (such as intestinal autoinfection) will be of greater significance in the case of articular rheumatism that tends to recidivate. Allergic disorders of the skin and mucosa are especially frequent in rheumatic patients and their families and are apparently related to rheumatic reactions. In the study of rheumatic patients, all modifications of the mesenchyma are of interest. Flatfoot in all forms is a regularly corresponding defect among enzygotic twins. In dizygotic twins lack of correspondence is as frequent as correspondence. In rheumatic patients flatfoot is nearly

always present. The pedal anomaly often manifested prior to the first attack of rheumatism may later become more prominent. In a pair of enzygotic twins, flatfoot is more pronounced in a rheumatic than in a nonrheumatic twin. A rheumatic diathesis is demonstrable earlier if the disorder runs a recidivating or chronic protracted course, even if only a milder form is manifested. Various types of rheumatism are observed coexistent in the same predisposed family. Differences that may amount to peculiar familial forms within are based on modifying factors of hereditary and nonhereditary nature. As hereditary factors, constitutional and metabolic anomalies may be observed, as exogenous influences (and these are now encountered more often than formerly) nutritional defects and vitamin deficiency.

Few studies of the heritability of exophthalmic goiter have been attempted. Dr W. Lehmann has undertaken research on this problem at the medical clinic of Breslau University. His material consists of twins and of patients' families. Thus far eight pairs of twins have been studied—three pairs of enzygotic twins and five pairs of dizygotic twins of the same sex. Correspondence was noted in two of the three enzygotic pairs with respect to hyperthyreosis whereas in the third pair no such correspondence was demonstrable. Of the dizygotic pairs one showed correspondence with respect to hyperthyreosis but no such correspondence was observed in the remaining three pairs. As the twins had been selected at random it was concluded on the basis of these observations that hereditary predisposition is a pathogenic factor in hyperthyreosis. In addition, a study has been made of the families of those patients who within the last few years were treated for exophthalmic goiter at the Breslau clinic. A vast amount of genealogical data is being collected so that in each case the familial picture will be as complete as possible. Thus far the families of twenty patients have been studied. In eleven of these families no record of other cases of exophthalmic goiter has as yet been found, conversely, in the other nine families investigated, twenty-eight other cases of hyperthyreosis, thyrotoxicosis and fully developed exophthalmic goiter were established. Of these twenty-eight cases, six were cases of fully developed exophthalmic goiter. The twenty-eight persons affected represented various degrees of consanguinity to the Breslau hospital patient. The frequently encountered transitional types of thyroid disorder that precede exophthalmic goiter may be interpreted as incomplete manifestations of the hereditary predisposition. The data elicited thus far suggest a dominant hereditary transmission of the predisposition to exophthalmic goiter. This dominance seems, however, not always to be regular. Lehmann's studies also show thyroid disturbances to be much more frequent in women than in men.

In a discussion of Lehmann's work Prof K. H. Bauer, ordinarius for surgery at Breslau, who for many years has been interested in genetic research, stated that familiar manifestation of thyroid dysfunction is rare and ought not to be overevaluated, the presence of a struma is no indication of a predisposition to exophthalmic goiter and the very existence of such a predisposition is questionable. In any event the operating surgeon seldom encounters more than one case of exophthalmic goiter within the same family.

Sterility in Marriage

The problem of sterility in marriage recently received full discussion in the Hamburg Medical Society. The first speaker, Dr H. Dietel of the Woman's Hospital of Hamburg University (Eppendorf) discussed 'Sterility: Its Cause and Treatment'. A clear definition of the term 'sterility' is necessary if we are to compare the statistics and observations contained in the literature. Dietel emphasizes on the grounds of the relatively brief period of a woman's fertility the necessity of suitable and timely therapy, the commencement of which should not be delayed beyond two years. If on examination the husband is

found capable of procreating, the principal causes of the sterility must be sought in the wife. Diabetes should receive special consideration. Treatment of extragenital disorders or malformations of the genitalia will differ according to the type and severity of the disease in question. Cervical catarrh is frequently a cause of sterility, if the usual methods fail, cervical curettage and scarification are indicated. In cervical stenosis, dilation of the uterine canal frequently leads to favorable results. Although uterine retroflexion may be a cause of sterility in some women, there are just as many women who become pregnant despite the presence of this anomaly. Before a surgical intervention is decided on, the permeability of the tubes should first be tested. With regard to hypoplasia, Dietel emphasizes that there is no uterus so small that a pregnancy cannot take place therein, even if the outlook is relatively bad. In the treatment of hypoplasia, glandular therapy occupies the first place at present. Professor Haselhorst of the Women's Hospital, Hamburg, stated that in his institution 1,000 mouse units of estrogen is administered orally on twenty-one days of each month for three months. If favorable results are not forthcoming, the dosage is increased to from 2,000 to 3,000 mouse units.

In conclusion, Prof. Hans Ritter, dermatologist, discussed "Sterility in the Male." In sexual hypofunction or dysfunction some favorable therapeutic results may be obtained if the condition is detected in time. But if a deficiency is first revealed only in the adult subject and through marriage, it is usually too late to institute an effective therapy. More frequently, however, male sterility results from infectious disease. Next to tuberculosis and syphilis, gonorrhea is the most important. Damage from this source is much more frequent than is commonly supposed, and although the condition may be only transitory it is often permanent. Ritter reports several observations gleaned from his study of the extract of the anterior lobe of the hypophysis. In two cases of sterility based on hypophysial cachexia, the characteristic eczema of this disorder disappeared with amazing rapidity under treatment with the extract. Ritter thereafter utilized the extract regularly in the treatment of chronic eczema and observed also a stimulation of sexual function, as regards both libido and sexual potency, in hundreds of cases so treated.

Accordingly he came to apply the same general therapy to cases of sexual debility and the results were striking. Even in cases of necrospemia the favorable response was amazing. In one case abundant quantities of motile spermatozoa were detected in the semen subsequent to fifty injections of the extract. In the course of one year Ritter was able by this means to restore the procreative capability of ten necrospemic patients. Nor should the progeny of these men be considered inferior, since spermatogenesis had not been affected. This therapy should be regarded as causal. The semen of the ten patients mentioned has remained normal subsequent to the cessation of treatment.

Typhoid Infection from Ice Cream

In the *Zeitschrift für Hygiene*, Dr. Roelcke of the Hygienic Institute in Heidelberg reports an outbreak of twenty-four cases of typhoid in children of a village in Baden. All these children became ill at about the same time, all were affected with diarrhea and vomiting and all complained of headache and abdominal pain. A diagnosis of typhoid was serologically established. The cases were atypical and mild. The period of incubation ranged from seven to twenty days. It was found to be the source of infection. It was found that the ice cream vendor's wife had succumbed to enteric infection at about the same time that the children had chased the ice cream and furthermore that the mother had experienced a mild gastro-enteric attack. This couple must have originated either the infection by the ice cream or by contact.

Prof. Fedor Krause Is Dead

Prof. Fedor Krause, one of the best known German surgeons, is dead at the age of 80. Krause's pioneering improvement of operative procedures won him a worldwide reputation. A pupil of Volkmann at Halle, he quickly rose in his profession. After having served as senior physician in several of the large hospitals he was appointed in 1900 director of the Augusta Hospital, Berlin, a post which he occupied until his retirement in 1921. Krause's reputation depended in addition to his work in bone and joint tuberculosis on his innovations in the surgery of the brain and spinal cord. His great contributions to the literature of the latter field were many times translated into foreign languages, including English. Krause's method of excision of the gasserian ganglion is designated in the literature as "Krause's operation." Krause, the man was a lovable personality and he was an active member of various medical organizations.

Prof. Carl Schleyer Is Dead

Prof. Carl R. Schleyer died in Berlin, aged 61. A pupil of C. Gerhardt, he was especially noted for his work in the field of nervous diseases and for the kidney test which bears his name. As first German internist and as director of the internal medical service of Augusta Hospital, Berlin, Schleyer established a diet kitchen which became a model for similar kitchens throughout Germany.

ITALY

Oct. 30, 1937

Dermatologic Meeting

The Società di Dermatologia e Sifilografia met at Messina under the chairmanship of Professor Tommasi, head of the clinic of Palermo, who reported the case of a woman suffering from primary gonococcal arthritis. The husband contracted gonorrhea and three weeks later the wife showed signs of fever and articular rheumatism with the clinical symptoms of gonorrheal arthritis. Examination of the genito-urinary tract were negative for the gonococcus. The speaker said that the case was one of primary gonococcal septicemia by direct entrance of gonococci into the blood and secondary location of the organisms in the joints. The absence of infection of the genitals was due to the fact that the woman took a preventive vaginal douche of potassium permanganate solution, on the advice of her husband.

Professors Monacelli and Fulchignoni of Messina reported the results of studies of tropical ulcer in Africans. In all cases the fusospirillar association was abundant. Fusiform bacilli were found at the surfaces and spirochetes were deeply located. The inoculation in animals gave negative results in all cases. Satisfactory results were obtained from topical applications and parenteral administration of vitamin A. The speakers believe that tropical ulcer originates in avitaminosis.

Professors Bosco and Nicastro of Palermo spoke on the staining of leprosy nodes by methylene blue. In 1934 Mouton reported satisfactory results from the intravenous injections of methylene blue in the treatment of leprosy. Methylene blue is retained by leprosy tissues, but it is not yet clear whether the stain is retained by leprosy bacilli, leprosy cells or reticulo-endothelial cells of the leprosy skin. Leprous erythema and infiltration that cannot be seen at clinical examination of a given leprosy lesion can be seen in the course of the treatment with methylene blue. Tommasi believes that the intravenous injections of methylene blue are of value in the early diagnosis of leprosy rather than in the treatment of the disease. The speakers found by experiments that the leprosy bacillus does not stain with methylene blue. Professor Scala of Messina stated that he administered intravenous injections of methylene blue to eleven lepers, with failure of the treatment.

Tommasi and Varvaro studied the influence of pneumo-inoculation in a normal lung in the evolution of cutaneous tubercles.

Two patients with normal lungs were suffering from elephantiasis of the legs and small lupus lesions on the face. Pneumothorax induced improvement of the local lesion, but the results were not permanent. Further studies are advisable.

Surgical Work in Military Hospitals

At the various military hospitals during 1936 the number of minor operations totaled 11,784, including 3,771 incisions of superficial abscesses and 1,920 reductions of fractures. The major operations totaled 6,511, which included 3,210 on the abdomen, 1,587 on the pelvis and pelvic organs and peritoneum and 902 on the head. The number of major operations is larger than in previous years because of the increased number of soldiers. There were 1,566 operations for hernia, which included 1,472 operations in inguinal or inguinoscrotal hernia, in which eleven cases were of strangulated hernias. In the group of abdominal operations, 1,416 were done in surgical conditions of the appendix. There were made 337 appendectomies with a mortality rate of 6.8 per cent. In the group of pelvic operations, thirty-three were done on the pelvis or pelvic soft parts, eight on the pelvic ureter, the bladder or the prostate, 826 on the rectum and posterior part of the peritoneum and 720 on the anterior part of it. There were 115 operations on the thorax, including sixty-two costal resections in empyema, pyopneumothorax and fistulas, with nine deaths in the group. There were 200 operations in benign tumors of various nature, nine operations for cancer, sixty-four for gastroduodenal ulcer and its complications and twenty-five operations on echinococcal cysts of the lung or the liver.

Physical Training on a National Scale

The present cabinet is pointing out the necessity of higher culture for the nation in general, and the home office is the center of the "cultural movement." During the summer the physical training of the nation was planned and successfully carried out throughout the country, partly because of the trouble with China. As physical training is one of the fundamental objects of the cultural movement, it was carefully planned, on a large scale, and advantage was taken of the twenty days after August 1 when all schools were having summer vacation. Every morning the Tokyo central broadcasting station broadcast gymnastic exercises. All the nation was advised to participate voluntarily for half an hour from 6 in the morning. The drill grounds were generally the primary school grounds, the precincts of shrines and temples, the parks, the seashore and factory courts. For the people, especially office and factory workers, who failed to take part in the morning exercise, thirty minutes after lunch was given over for this purpose. The primary school children were requested to participate in the gymnastics. In the villages at least one member of each family was obliged to take part. At the offices chiefs and clerks were advised to do the exercises, and members of the Japan Young Men's Association and ex-soldiers were summoned to the grounds to assist in controlling and regulating the assemblages. It is estimated that 10,000,000 men and children participated throughout the country. These morning exercises, besides improving the nation's health, must have done much to cultivate a cooperative spirit.

Physical Examination of All Citizens in Osaka

The municipal office of Osaka, a great industrial city with a population of 2,500,000 has drafted a plan for promoting the health of its citizens. This plan will be put into effect by a committee of four sections. The first section will deal with the sanitary surroundings of the city and the health of the laboring people. The second section will instruct housewives concerning nutrition and the care of young children and babies.

The third section will act as adviser to the schools to see that sanitary equipment is provided, and will otherwise aid in promoting the health of school children. The fourth section is to work in the field of preventive medicine. The committee will first promote the physical examination of the citizens of Osaka, this work will be carried on by the twelve health offices which have already been established. Each office will supervise the examination of 60,000 citizens. The reports will include the following information: how many members of the family have died particularly infants; the number of workers in the family; the number who have been dismissed or are out of employment and the causes of dismissal; the lighting, the humidity of the dwelling houses and the workshops and the amount of noise will be reported. Concerning the individual citizen, the examination will inquire into his habits, tastes, occupation, office hours, leisure hours, monthly income, medical history, hours of sleep, cough, sputum, night-sweats, fatigue, tendency to catch cold, stomach complaints and the price and ingredients of his lunch. Moreover, the general physical examination will include a report on height, weight and chest expansion. When tuberculosis is suspected the subject will be summoned to the office for x-ray examination. Such an elaborate examination has never been done in any place in this country. A few years ago, the government at Osaka tried to accomplish something of this kind by distributing report cards to be filled in and returned voluntarily, but the plan was a failure for various reasons. Now the authorities have decided to have the doctor call at each house and render a report, and every police station will assist in carrying out the plan.

In conjunction with this movement, the authorities will establish a Women's Health Association, which will use the various health offices as centers of activity. This association will teach household sanitation and similar subjects, such as how to render first aid in emergencies and how to determine the quality of drinking water, to housewives. Women are being trained to be the regular guards of their homes against enemy's planes during air raids, as the men will be away from home. They will be given lectures on poison gases and on how to deal with the gas from aerial bombs. The central training places will be the health office, infants' homes and maternity hospitals in each district.

Dr. Mita Appointed President of University

The appointment of Prof. Dr. S. Mita as president of the Formosan Imperial University was announced September 1. He has been dean of the medical college of the university. Of the eight presidents of governmental universities in this country, three are medical men, excluding one who recently resigned. This fact shows that medical men are highly regarded in the academic world here. However, a great statesman who has been a physician cannot be found; the physician is evidently inclined to refuse to wander into a political broad.

The Japan Research Institute of Industry and Labor

The Japan Research Institute of Industry and Labor, supported by the Japan Science Association, has decided to equip various buildings for its research work in Tokyo at a cost of 1,102,000 yen. The institute has laboratories, a library, a museum of industry and labor, a school of industry and labor and assembly halls. There will also be laboratories for study of the prevention of occupational diseases. Equipment will be provided for the study of both the physical and the spiritual conditions necessary for efficiency in labor. However much industry is mechanized, it will be impossible to cease employing human muscular labor, furthermore human muscles will be required to work more speedily and to be more delicate and enduring. In these laboratories the training of muscles along these lines is to be the subject of research. An instrument is to be furnished to investigate the various phases of biologic

electricity which accompany muscular exertion. In the laboratory for investigating fatigue, the chief studies will relate to nerve control. The rehabilitation of the disabled and the deformed will be undertaken by the most modern methods. The cost of living and the wages paid for labor are to be subjects of an investigation. Factory sanitation and the development of the laborers' physique will be thoroughly studied. The chief of the institute will be Dr. Y. Teruoka, formerly chief of the Kurashiki Labor Research Institute and now adviser to the central government on labor problems.

Subcutaneous Vaccination Remains Unapproved

The subcutaneous vaccination introduced by Dr. Yaoi of the Infectious Disease Research Institute is meeting great favor among mothers, for it leaves no scars on the arms, which many girls like to keep bare. Some practitioners, by advertising this method, overrate its convenience. There arose some trouble about the vaccination certificate, and so the sanitary department of the metropolitan police board has announced that subcutaneous vaccination is still of doubtful effect. The home office therefore has no intention of approving this method as trustworthy at present. Vaccination must be certified only after the usual cutaneous vaccination has been successful.

BELGIUM

(From Our Regular Correspondent)

Oct. 11, 1937

Physical Education in the Schools

The Societe Medicale Belge d'Education Physique et de Sports investigated the situation in the schools with respect to the physical education of children who exhibit physical or mental abnormality. The society proposed to make certain recommendations with respect to school children whose condition bordered on the pathologic. The investigating committees met from time to time under the joint chairmanship of Professor de Munter of the University of Liege and Dr. J. De Vaucleeroy, chief medical officer of Brussels schools.

The report of the committees was discussed by the society at two of its general assemblies and the following conclusions were adopted:

1 The rehabilitation of physically subnormal children has been the function of the special colony, the preventorium, and so on. The school medical officer has merely to designate the children in question and observe their reactions. The application of suitable corrective measures should be confided under medical supervision, to the teacher, the nurse, the dietitian, the monitress and the instructor in physical education.

2 A school should devote itself to a program of physical education suitable for all its pupils. The school doctor should indicate to the teacher those children who present physical anomalies and should furnish the parents useful information and advice so that these children may receive proper care. The school physician should not undertake medical treatment of the children.

3 After the schools have adopted well organized programs of physical education for all the pupil population, special classes in corrective gymnastics will be organized in the larger centers. The instructor of a special class will be a graduate in physical education and its membership will be selected according to the recommendations of the school medical officer who in addition will divide the pupils into various groups and point out the requisite measures. The pupils in the special class will be of all be differentiated on the basis of respiratory, circulatory and vertebral defects. Pathologic cases will be referred to an orthopedist.

4 A graduate instructor in physical education is a dispensable member of the staff of any educational institution. Mentally abnormal children if the optimal mental development is to be assured.

Occupational Diseases Among Workers in the Chromates

Uytendoeff addressed the Society of Industrial Medicine on the prevalence of occupational disorders in such chemical industries as tanning and chromium plating. He has especially investigated conditions among workers in the chromates which are prepared from the chromite ore. The toxicity of different products varies but that of the alkaline chromates and the bichromates is considerable. The last named substances may underlie several types of dermatitis, ulcerations and disturbances of the upper respiratory organs such as rhinitis and perforation of the nasal septum. Other frequent manifestations among the workers are conjunctivitis and ulcerous lesions of the buccal cavity, the tonsils and the pharynx. Generalized intoxication seems to be exceptional. The lesions are caused by the dusts, vapors and various products given off in the course of the manufacturing process.

Although prophylaxis has been introduced, it is largely ineffectual owing to the negligence of the workers themselves. All are affected with rhinitis, a majority with perforation of the nasal septum and some with dermatitis of the legs and forearms. Many workers present hollow cicatrices produced by chromium. The author envisages a prophylaxis compatible with the exigencies of the work. Helpful protective measures would be the use of closed vessels for certain chemical procedures, adequate ventilation of work rooms, installation of showerbaths and locker rooms, and the wearing of masks and rubber gloves. Careful selection of workers hired, periodic physical examinations of workers and their proper instruction in the prophylactic routine should be considered fundamental.

International Committee to Combat Charlatanism

The International Committee to Combat Charlatanism met recently in Brussels. The first theme, introduced by Dr. Brandligt, was "Quackery in Neighboring Countries." The speaker reminded his audience that the "big time" quacks are cosmopolites, always on the move, so it is useless to designate them as of this or that nationality. Dr. Boëlle spoke of conditions in France.

The second topic, "Midwives and Practical Nurses," was discussed by Dr. Boëlle with special reference to present legal regulation of midwives in France. Dr. Gildemyn discussed the problem of practical nurses and the reason why no action has thus far been taken to curb the illegal practices of these women. Dr. Gildemyn submitted a paper on physicians who permit their names to be used in connection with nefarious enterprises. This problem is rendered particularly distressing by the fact that the doctor who acts merely as straw man for an illegal enterprise is difficult to prosecute on this ground alone. Dr. Boëlle and Dr. d'Ernst described the existing laws of their respective countries.

Marriages

AUSTIN J. BROGAN, Eastport, Maine, to Miss Mary Edmiston of Bellwood, Pa., in Germantown, Pa., July 10.

WILLIAM KITCHIN McDOWELL, Scotland Neck, N. C., to Miss Frances Morton of Greenville, October 27.

ANDREW DU VAL TAYLOR, Charlotte, N. C., to Miss Anne Jessup O'Sullivan of Hertford, June 5.

PAUL M. RICE, Chicago, to Miss Mary M. Gardner of Baltimore, May 12, at Santa Fe, N. M.

WILLIAM A. SNOODGRASS JR. to Miss Mary Jane Moseley of Warren, Ark., Aug. 7.

CHARLES M. STARR, Larned, Kan., to Miss Helen Burbank of Los Angeles, September 19.

JOHN M. USOW, Milwaukee, to Miss Ella Mae Goodman of Norfolk, Va., October 10.

WILLIAM B. WILD to Miss Priscilla Mary Barry both of Ireland, November 12.

Deaths

John Laidlaw Buel, Litchfield, Conn., College of Physicians and Surgeons Medical Department of Columbia College New York, 1888, member of the Connecticut State Medical Society, chairman of the board of education formerly member of the state legislature, on the staffs of the Spring Hill Sanitarium Winsted and the Charlotte Hungerford Hospital Torrington, aged 75 died September 1 in the Sharon (Conn.) Hospital, of arteriosclerosis, hypertrophy of the prostate and bronchopneumonia

Charles Benjamin Noecker ☉ Chinchilla, Pa., University of Pennsylvania Department of Medicine, Philadelphia 1902, fellow of the American College of Surgeons, formerly surgeon to the Scranton (Pa.) State Hospital consulting surgeon to the West Side Hospital and Mercy Hospital, Scranton Mid-Valley Hospital, Peckville, and St Joseph's Hospital Carbon-dale, aged 63, died, September 14, of multiple sclerosis and acute dilatation of the heart

Arthur David Haverstock, Seward Alaska Medical Department of Hamline University, Minneapolis 1909, past president of the Alaska Territorial Medical Association, at one time captain in the M. C. U. S. Army and acting assistant surgeon in the U. S. Public Health Service, member of the board of medical examiners, on the staff of the Seward General Hospital, aged 53, died, September 10 in Monrovia Calif, of tuberculosis

Joseph Samenfeld ☉ Brooklyn University and Bellevue Hospital Medical College New York, 1904, fellow of the American College of Physicians, attending physician to the Greenpoint and St Catherine's hospitals adjunct attending physician to the Jewish Hospital, consulting physician to the Williamsburgh Maternity and Lutheran hospitals aged 60, died September 5, in Germany, of heart disease while touring

Robert Morgan Entwisle ☉ Pittsburgh, University of Pennsylvania School of Medicine, Philadelphia 1914 instructor in surgery, University of Pittsburgh School of Medicine, fellow of the American College of Surgeons, on the staffs of St Francis Hospital, St Michael's Hospital, St Margaret Memorial Hospital, Presbyterian Hospital and the Children's Hospital aged 50, died, September 20, in Cleveland of coronary sclerosis

Rae Shepard Dorsett ☉ Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1900, formerly associate professor of medicine, Temple University School of Medicine Philadelphia, for three years assistant demonstrator of anatomy at his alma mater, attending physician to the Garretson Hospital, served during the World War, aged 62, died, September 28 of heart disease and diabetes mellitus

Cyril James Larkin, Chicago University of Illinois College of Medicine, Chicago, 1915, member of the Illinois State Medical Society, assistant clinical professor of surgery, Loyola University School of Medicine fellow of the American College of Surgeons, on the staff of the Mercy Hospital, aged 45 died September 3 at St Agnes Hospital Fond Du Lac Wis, of injuries received in an automobile accident

William Lee Secor ☉ Kerrville, Texas, Jefferson Medical College of Philadelphia, 1906 fellow of the American College of Surgeons served during the World War at one time professor of experimental physiology and physiologic chemistry at the American College of Medicine and Surgery Chicago chief of staff of the Kerrville Clinic and Secor Hospital aged 58 died September 26, of cerebral hemorrhage

Augustus Bruce Bailey, Portland Ore Willamette University Medical Department Salem 1904 member of the Oregon State Medical Society member of the Pacific Coast Otolaryngological Society fellow of the American College of Surgeons formerly mayor of Hillsboro on the staff of the Good Samaritan Hospital aged 63, died, September 12, of cirrhosis of the liver

Theodore Albinus Coffelt, Powersite Mo., Missouri Medical College St Louis, 1886 member of the Missouri State Medical Association member of the American Academy of Ophthalmology and Otolaryngology president of the Taney County Medical Society formerly on the staff of the Springfield (Mo.) Hospital aged 82, died September 6 of cerebral hemorrhage

Charles Eldridge Stevenson, Sheridan Wyo Omaha (Neb.) Medical College 1895 past president of Wyoming State Board of Medical Examiners and of the Sheridan County Medical Society formerly health officer and coroner aged 74 died September 12 in the Sheridan County Memorial Hospital of cerebral hemorrhage and pneumonia

Jeremiah Barrett Sullivan, New Haven, Conn., Yale University School of Medicine, New Haven 1906, member of the Connecticut State Medical Society, fellow of the American College of Surgeons, served during the World War, attending surgeon to St Raphael's Hospital, aged 57, died, September 1, of uremia and tumor of the kidney

Charles W. Tucker, Drakes Branch, Va., Medical College of Virginia Richmond, 1903, member of the Medical Society of Virginia chairman of the county board of supervisors, secretary of the county board of health, on the staff of the Southside Hospital, Farmville, aged 60, died, September 12, of hypertension and arteriosclerosis

Maria Emma Drew, Quincy Mass College of Physicians and Surgeons, Boston, 1894, Tufts College Medical School, Boston, 1895, member of the Massachusetts Medical Society, at one time school physician formerly on the staff of the Quincy City Hospital, aged 67, died, September 12, of carcinoma of the small intestine

Quintus Colton Fuller ☉ Milford, Iowa, Drake University Medical Department, Des Moines, 1892, for many years member of the board of education, fellow of the American College of Surgeons, superintendent and owner of the Milford Hospital, aged 70, was killed September 24, in an automobile accident near Sioux Rapids

John Andrew Dodd ☉ Marion Ohio, Western Reserve University School of Medicine, Cleveland, 1913, served during the World War, past president of the Marion Academy of Medicine, formerly on the staff of the Marion City Hospital, aged 55, died, September 9, in Cleveland, of carcinoma of the sigmoid

Melvin George Preston ☉ Utica, N. Y., Cornell University Medical College, New York, 1925, member of the Associated Anesthetists of the United States and Canada, on the staff of St Luke's Hospital aged 36, died, September 1, in the Manhattan General Hospital, New York, following an operation for hernia

Henry Grady Atherton, Jasper, Ga., Atlanta Medical College, 1915, member of the Medical Association of Georgia mayor of Jasper for many years member of the city council chairman of the board of trustees of the Pickens County High School, aged 47, died, September 4, of congestive heart disease

John Elijah Loveland, Middletown, Conn., Harvard University Medical School, Boston, 1893, member of the Connecticut State Medical Society, fellow of the American College of Surgeons on the staff of the Middlesex Hospital, aged 72, died, September 12, of cerebral hemorrhage

Henry La Motte ☉ P. A. S., Lieut Commander, U. S. Navy, retired, La Mesa, Calif University of Pennsylvania Department of Medicine Philadelphia, 1889, entered the navy in 1892 and retired in 1897 served during the Spanish-American and World wars aged 70, died, September 4

Haydn Lyle Fischer, Ottawa Ill., Northwestern University Medical School, Chicago, 1909, member of the Illinois State Medical Society, served during the World War, past president of the Henry County Medical Society, aged 53, died suddenly, September 4, of angina pectoris

Clifton Z. Robbins, Bloomsburg Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1895 member of the Medical Society of the State of Pennsylvania, past president of the Columbia County Medical Society, aged 64, died, September 27, of myocarditis

Arthur Groman Noehren, Allahabad, India, University of Virginia Department of Medicine, Charlottesville, 1922, a medical missionary, formerly college physician to the Williams College, Williamstown, Mass, aged 52, died suddenly, September 15, of heart disease

Robert William Sayre ☉ Point Pleasant, W. Va., National University of Arts and Sciences Medical Department, St Louis, 1915, president of the county school board, and county health officer served during the World War, aged 43, died, September 18 of hypertension

Maurice Hopkins Maxwell, Keosauqua, W. Va., George Washington University School of Medicine Washington D. C., 1908, member of the West Virginia State Medical Association aged 53 on the staff of the Potomac Valley Hospital, where he died September 7

Floyd Hamilton Randall ☉ Van Wert Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, member of the West Virginia State Medical Association served during the World War aged 62 died September 16 of diabetes mellitus

George Kendall Heidler, Cleveland Heights, Ohio, Western Reserve University Medical Department, Cleveland, 1898, member of the Ohio State Medical Association, aged 70, died, August 26, of arteriosclerosis, cerebral hemorrhage and hypertension

Amos D Bates, Camp Point, Ill., Chicago Medical College, 1882, member of the Illinois State Medical Society, aged 82, died, September 6, at St Margaret's Hospital, Spring Valley, of hypostatic pneumonia as a result of a fall and fracture of the right leg

Bert Chamberlain Kern Ⓢ Jackson, Calif., Washington University School of Medicine, St Louis, 1905, formerly on the staff of the Preston School of Industry, Waterman, aged 56, died, September 5, in the Sutter Hospital, Sacramento, of heart disease

Adelaide Dutcher Ⓢ Syracuse, N. Y., Johns Hopkins University School of Medicine, Baltimore, 1901, aged 63 for many years on the staff of the Syracuse Memorial Hospital, where she died, September 11, of carcinoma of the breast and abdominal organs

Harry Lee Alexander, McKenzie, Tenn., University of the South Medical Department, Seawanee, 1901, member of the Tennessee State Medical Association, served during the World War, aged 61, died suddenly, September 7, of heart disease

William Chalmers Wills, Victoria, Va., University of Virginia Department of Medicine, Charlottesville, 1930, member of the Medical Society of Virginia, aged 35, died in August, in the Tucker Sanatorium, Richmond, of septicemia

Max Kahn Ⓢ Baltimore, College of Physicians and Surgeons, Baltimore, 1905, member of the Radiological Society of North America, on the staff of the Bon Secours Hospital, aged 54, died, September 23, of coronary thrombosis

Wilmer Ridgway Batt, Spring House, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1884, formerly registrar of vital statistics for the state department of health, aged 76, died, September 13, of myocarditis

William Hewstone Raymenton, San Diego, Calif., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1873, aged 85, died, September 11, of cerebral hemorrhage and arteriosclerosis

Willard Lyman Wright Ⓢ Boston, Tufts College Medical School, Boston, 1915, served during the World War member of the American Urological Association, instructor in urology at his alma mater, aged 48, died, August 18

John W Sarpolis Ⓢ Glenlyon, Pa., Loyola University School of Medicine, Chicago, 1919, on the staff of the Nanticoke (Pa.) State Hospital, aged 41, died suddenly, September 16, of paraldehyde poisoning, self administered

George Carson Hanna Ⓢ Philadelphia, Medico-Chirurgical College of Philadelphia, 1895, fellow of the American College of Surgeons, chief of obstetrics, Frankford Hospital, aged 66, died, September 13, of cerebral hemorrhage

John Nisbet Gunn, Calgary, Alta., Canada University of Toronto Faculty of Medicine, 1902 M.R.C.S. England and L.R.C.P. London, 1903, fellow of the American College of Surgeons, aged 58, died, August 26

George Hicks Martindale, Hope, Ark., Chattanooga (Tenn.) Medical College, 1899 past president of the Hempstead County Medical Society, county health officer, aged 70 died September 9, of bronchopneumonia

Frederick Sumner Selby Ⓢ Chicago, Rush Medical College, Chicago, 1893, aged 65, on the staff of the Garfield Hospital, where he died, September 27, of empyema of the gall bladder and chronic myocarditis

Irwin Henry Schmidt Ⓢ Faulkton, S. D., St. Louis University School of Medicine, 1916 served during the World War, on the staff of the Faulk County Hospital, aged 45 died September 1, of brain tumor

Otmar Thurlimann, Harvey, Ill., Rush Medical College, Chicago, 1925, member of the Illinois State Medical Society, aged 37, died, September 14, in a hospital at Duluth, Minn., of streptococcal meningitis

Charles Thomas Martin, Brownsville, Tenn., University of Nashville (Tenn.) Medical Department, 1897, died, September 7, in a hospital at Nashville, of carcinoma of the prostate

Edwin Francis Hagedorn, Modest, Cal., University of California Medical College, 1908, member of the California Medical Association, aged 52, died, September 7, of dilatation of the heart

Archer Avery, Atlanta, Ga., Southern Medical College, Atlanta, 1880, member of the Medical Association of Georgia, Confederate veteran, aged 90, died, September 12, of arterial vascular disease

Robert S Lynd, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1884, aged 81, died, September 11, in the Presbyterian Hospital, of intestinal obstruction

Joseph Hart Hiden Ⓢ Pungoteague, Va., Medical College of Virginia, Richmond, 1897, formerly a minister served during the World War, aged 71, died, September 10, of coronary occlusion

Leroy Worth Baxter Ⓢ Joplin, Mo., Rush Medical College, Chicago, 1906, aged 56, on the staffs of St. John's Hospital and the Freeman Hospital, where he died, September 2, of coronary occlusion

Paul Preston Oliver, Shawnee, Okla. (licensed in Texas under the Act of 1907), also a pharmacist and a minister, aged 57, died, September 2, at Mayhill, N. M., of coronary thrombosis

Edwin M Easley, Bacons Castle, Va., Medical College of Virginia, Richmond, 1900 member of the Medical Society of Virginia, aged 62, died, September 15, in an automobile accident

Humphrey John Falvey, Worcester, Mass., Baltimore Medical College, 1901, served during the World War, aged 62 died suddenly, September 4, of carcinoma of the prostate

Alfred Joseph Giguere Ⓢ Lowell, Mass., University of Vermont College of Medicine, Burlington, 1907, aged 62, died, September 2, of diabetes mellitus and coronary thrombosis

William Robert Talbot, Newcastle, Neb., Sioux City (Iowa) College of Medicine, 1893, aged 72, died, September 4, in a hospital at Omaha, of acute lymphatic leukemia

Herbert J Baldwin Ⓢ Philadelphia, Jefferson Medical College of Philadelphia, 1908, aged 52, died, September 14 in the Lankenau Hospital, of pulmonary edema

William Allen Evans, Lakewood, Ohio, Jefferson Medical College of Philadelphia, 1906, aged 63 died, September 16, of angina pectoris and coronary thrombosis

Timothy Joseph Daly, Lawrence, Mass., Harvard University Medical School, Boston, 1897, aged 64, died suddenly, September 6, of cerebral hemorrhage

James A D Hite, Nashville, Tenn. (licensed in Tennessee in 1891), aged 67, died, September 4, of pneumonia, chronic nephritis and cirrhosis of the liver

William Clovis Cummings, Oklahoma City, Chicago College of Medicine and Surgery, 1909, aged 55, died, September 5 in a local hospital, of heart disease

Thomas E Thames, Montgomery, La., Memphis (Tenn.) Hospital Medical College, 1911, aged 55, died, September 2 at Pineville, of cerebral hemorrhage

Walter Jordan Jackson, Baltimore, Howard University College of Medicine, Washington, D. C. 1913, aged 47, died, September 11, of myocarditis

William R Dale, Sumner, Ill., University of Louisville (Ky.) Medical Department, 1877, aged 83, died, September 22 of coronary thrombosis

Jamison Vawter, Arkansas City, Kan., University of Louisville (Ky.) Medical Department, 1878, aged 80 died in August at the Mercy Hospital

Archibald Jameson, Arnprior, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1886, L.S.A., London, 1887, died, August 19

Leon Clarke Robertson, San Diego, Calif., Rush Medical College, Chicago, 1887, aged 73, died, September 26 of duodenal ulcer and hemorrhage

Herbert Abraham Robinson, Kenosha, Wis., Rush Medical College, Chicago, 1889, aged 73, died, September 17 of coronary thrombosis

Robert Lee Snow, Biloxi, Miss., Hahnemann Medical College and Hospital, Chicago, 1892, aged 72, died, August 1 of angina pectoris

Charles Oliver Hart, Pittsfield, N. H. (licensed in Massachusetts under the Act of 1895), aged 78, died, August 1

Daniel M Sanders, Chilhowie, Va., Medical College of Virginia, Richmond, 1899, aged 65 died, September 12

Thomas J Tenney, Detroit, Detroit College of Medicine, 1907, aged 52, died, September 9, of heart disease

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

McLeans (Dr J H) Universal Liver Pills—Dr J H McLean Medicine Co, St Louis Composition Extracts of plant drugs including a laxative Fraudulent therapeutic claims—[N J 25098 July 1936]

Chamberlain's Salve—Chamberlain Medicine Co Des Moines Composition Essentially ammoniated mercury in a petrolatum and paraffin base For eczema salt rheum piles etc Fraudulent therapeutic claims—[N J 25098 July 1936]

Hobsons (Dr) Whooping Cough Syrup—Pfeiffer Chemical Co New York and St Louis Composition Essentially ammonium chloride chloroform (1.02 mms per fluid ounce) and a compound of antimony with pine tar sugar and water Fraudulent therapeutic claims—[N J 25098 July 1936]

Candy Worm Expeller—Furst McNess Co and Furst & Thomas Freeport Ill Composition Essentially pink compressed tablets each containing chiefly sugars about 0.4 grain of syntonin and a small amount of coloring matter Fraudulent therapeutic claims—[N J 25101 July 1936]

Powers Asthma Relief—E C Powers Co Boston Composition Essentially saltpeter and plant material including stramonium Fraudulent therapeutic claims—[N J 25102 July 1936]

Roo Mo Rub—Roo-Mo-Rub Corp Philadelphia Composition Essentially alcohol (80 per cent) water and a small proportion of wintergreen oil For rheumatism swollen glands and joints erysipelas boils scarlet fever etc Fraudulent therapeutic claims—[N J 25103 July 1936]

Red Fire Ointment—Harwell Co Chicago Composition Essentially salicylic acid (14.26 per cent) and volatile oils including menthol and wintergreen in a fatty base For various types of rheumatism Fraudulent therapeutic claims—[N J 25107 July 1936]

Ehrlich's (Dr) Nerve Tonic and Sedative—Dr Ehrlich's Laboratory Cleveland Composition A watery solution containing phenobarbital and bromides of sodium and ammonium Misbranded because labeled to contain no habit forming drugs and because of fraudulent therapeutic claims—[V J 25112 July 1936]

Ehrlich's (Dr) Tonic and Blood Purifier—Dr Ehrlich's Laboratory Cleveland Composition Essentially methenamine an iron compound potassium iodide extracts of plant drugs sugar and water Fraudulently represented as a remedy for rheumatism neuritis blood and nerve disorders etc—[N J 25112 July 1936]

Ehrlich's (Dr) Kidney and Bladder Medicine—Dr Ehrlich's Laboratory Cleveland Composition Essentially methenamine (0.36 grams per 100 milliliters) extracts of laxative plant drugs a small proportion of an iron compound and water Fraudulent therapeutic claims—[N J 25112 July 1936]

Nature's Vital Food—Charles J Roode North Stonington Conn Composition Essentially ground plant material extracts of plant drugs including rhubarb sarsaparilla podophyllum mullein and senna with water and salicylic acid (0.1 per cent) Fraudulently represented as a remedy for impure blood and a prevention of cancers tumors syphilis etc—[N J 25116 July 1936]

Oceanic Vitex—Neu Life Laboratories Sacramento Calif Composition Essentially seaweed Fraudulently represented as a nerve and gland food and a remedy for rheumatism kidney and blood disorders goiter asthma etc—[N J 25117 July 1936]

Udga Tablets—Udga Inc St Paul Minn Composition Approximately 9 grains each of baking soda and bismuth subnitrate and 8 grains of magnesium oxide per tablet Fraudulently represented as a remedy for acidosis chronic gastritis indigestion stomach ulcers etc—[N J 25118 July 1936]

Athollin—Hilliard Products Co Inc Wilmington Del Composition Essentially boric benzoic and salicylic acids aluminum chloride alcohol (72.7 per cent by volume) water and perfume For skin disorders such as pimples acne and eczema Fraudulent therapeutic claims—[N J 25119 July 1936]

Glo More Shampoo—Gilmore Burke Inc Seattle Composition Essentially soap a trace of alcohol water and an unnamed agent which rendered it antiseptic when diluted with one volume of water but which failed to render it anti-epic when diluted with nine volumes of water Fraudulently represented as to its alleged healing and antiseptic qualities—[N J 25121 July 1936]

Stollgal—Sto-Li Gal Co St Paul Minn Composition White tablets containing baking soda (0.46 gram) bismuth subnitrate (0.31 gram) calcium carbonate (0.15 gram) calcium phosphate (0.14 gram) and magnesium oxide (0.28 gram) and menthol flavoring in each pink tablet, calcium carbonates phenolphthalein and extractive material including a resin For high blood pressure debility stomach disorders including ulcers etc Fraudulent therapeutic claims—[V J 25124 July 1936]

Quan Da Sae—Seebasco Laboratories Inc Philadelphia Composition Essentially a volatile oil such as camphor oil (16 per cent) and a small proportion of a phenolic substance in petrolatum Fraudulently represented as a remedy for various types of inflammation—[N J 25125 July 1936]

Hem O Rem—Seebasco Laboratories Inc Philadelphia Composition Extracts of plant drugs including a resin and a trace of an alkaloid with alcohol (62.7 per cent) and water Fraudulently represented as an effective internal remedy for hemorrhoids—[N J 25125 July 1936]

Laxated H L C—Durham Drug Co Ittadena Miss Composition Essentially water calcium iron epsom salt sodium benzoate and plant extracts For stomach kidney and bladder disorders etc Fraudulent therapeutic claims—[N J 25129 August 1936]

Armstrong's Sore Throat and Quinsy Drops—Nelson Baker & Co Detroit Composition Essentially water alcohol acetic acid and extracts of plant drugs including red pepper and bloodroot Fraudulent therapeutic claims—[N J 25132 August 1936]

Holford's Inhaler—William J Fink trading as the Holford Co Minneapolis Composition Essentially plant material including lavender flowers mustard seeds and mustard oil For catarrh hay fever asthma sinus trouble etc Fraudulent therapeutic claims—[N J 25134 August 1936]

Ben Arid's Desert Remedy—Mountain & Desert Products Co Denver Composition A dried and cut plant of a species of Ephedra For asthma indigestion insomnia neuritis kidney and bladder disorders rheumatism high blood pressure etc Fraudulent therapeutic claims—[N J 25135 August 1936]

Risal Liquor Cresolls Compound—Teres and Solomon Turk trading as Turk Drug Co Philadelphia Composition A small proportion of a potassium compound less than 5 per cent of a fatty anhydride about 5 per cent of tar acids a small proportion of glycerin and water For feminine hygiene and athlete's foot Not antiseptic False and misleading therapeutic claims—[N J 25177 August 1936]

Nu Vigor Tablets—C H Williams trading as the Pier Co New York Composition Compounds of iron manganese and quinine with traces of sulfates and phosphates For nervousness debility neurasthenia impotence prostatic disorders etc Fraudulent therapeutic claims—[N J 25136 August 1936]

Femilene Antiseptic Tablets—Morris Products Co Urbana Ohio Composition Essentially sugar of milk tartaric acid and baking soda Not antiseptic Fraudulent therapeutic claims—[N J 25135 August 1936]

Sumner's Lung Salve—Dr J B Sumner & Son Provo and Orem Utah Composition Essentially eucalyptus oil and petrolatum For croup pneumonia and all throat and lung diseases Fraudulent therapeutic claims—[N J 25139 August 1936]

Preelson Pills—Laboratories Inc and Dewey W Miles Joplin Mo Composition Magnesium carbonate potassium nitrate and plant material including bearberry and buchu with sugar and chalk coating For kidney and bladder disorders Fraudulent therapeutic claims—[N J 25148 August 1936]

Dalley's Pain Extractor—Dalley Mfg Co Bayonne N J Composition Essentially a bismuth compound and camphor in an ointment base For hemorrhoids ulcers boils rheumatism erysipelas etc Fraudulent therapeutic claims—[N J 25140 August 1936]

Oil de Vita—Vita Laboratories Philadelphia Composition Essentially peppermint oil For destroying cold and catarrhal pus bacilli Fraudulent therapeutic claims—[N J 25144 August 1936]

American Desert Tea—American Desert Tea Co Hollywood Calif Composition A species of Ephedra For stomach kidney and bladder disorders insomnia rheumatism impure blood etc Fraudulent therapeutic claims—[N J 25141 August 1936]

Universal Pain Expeller—Chicago Drug Sales Co Chicago Composition Essentially ammonia a pungent principle such as red pepper a small proportion of a volatile oil and water For rheumatism neuralgia colds etc Fraudulent therapeutic claims—[N J 25143 August 1936]

Universal Brand Liniment—Chicago Drug Sales Co Chicago Composition Essentially an ammonium soap and volatile oils including camphor with alcohol and water colored green Fraudulent therapeutic claims—[V J 25143 August 1936]

Vita Pine Bathol—Vita Laboratories Philadelphia Composition Essentially soap and water perfumed with pine needle oil and colored For rheumatic conditions etc Fraudulent therapeutic claims—[N J 25144 August 1936]

Precision Rheumatic Relief Tablets—Laboratories Inc and Dewey W Miles Joplin Mo Composition Aspirin (5 grains per tablet) and plant material including calcichum Fraudulent therapeutic claims—[N J 25148 August 1936]

DANGEROUS PROMOTION BY DETAIL MEN

To the Editor—It seems to me that this sulfanilamide episode has afforded an opportunity to warn some of our better drug manufacturing companies against their high powered salesmanship to druggists and doctors. For example, various druggists have been informed that sulfanilamide is the proper treatment for acute gonorrhea. Consequently, in both towns and cities, sulfanilamide is being sold over the counter to the layman. Another example is the recommendation of Lilly's oval vaccines, such as Entoral, to their druggists. As a result, druggists have been carrying advertisements in the newspaper such as in this town—"Why take cold shots when you can take cold capsules?"

The same semisecret purpose in the production of drug products that prompted the production of Elivar of Sulfanilamide-Massengill has introduced a spirit of commercialism among drug manufacturing companies that is most harmful. This commercialism is well shown in the various unscientific names applied to drug products in an attempt to divert the attention of the doctor from their actual chemical content. I, as a practitioner in a small town, am familiar with the high powered salesmanship and unscientific presentation of facts by most drug salesmen, even from our bigger companies.

A. B. RICHTER, M.D., Flora, Ind.

DISTRIBUTION OF ANTIPNEUMOCOCCUS SERUM IN MASSACHUSETTS

To the Editor—In THE JOURNAL, October 23, there is published a report of the Committee on Public Health Relations of the New York Academy of Medicine, on Community Provision for the Serum Treatment of Pneumococcal Pneumonias.

In the paragraph on page 1326 describing the procedure for general distribution of antipneumococcus serum in Massachusetts, it states that no serum is given until the laboratory report indicates that the patient for whom it is requested is suffering from type I or type II infection and that only for patients who have been ill for not more than four days.

That was our practice up to March 1937, when the restriction as to the day of disease on which treatment with serum could be begun was withdrawn.

We have also made type V serum available on the same basis.

HENRY D. CHADWICK, M.D., Boston
Commissioner of Public Health,
Commonwealth of Massachusetts

SUPPURATIVE PERICARDITIS AND ITS SURGICAL DRAINAGE

To the Editor—In a recent article (Shuplev, A. M. Pericarditis, THE JOURNAL, September 25, p. 1017) the author states that "in late cases with a large effusion anterior drainage may not be effective" and that Truesdale, Heuer, Loucks, Moore and I have reported a 'posterolateral approach' as far as the pericardium is concerned, by resection of the seventh rib near the mediastinal line."

It is true that I discussed this approach in a paper before the Western Surgical Association December 1933, and to condemn it. I said that in the largest effusions fluid could be readily reached in this manner, but in the prompt expansion of the lung would require a large incision while in the smaller effusions such as in acute Pericarditis. Description of a posterolateral approach

Was Made Through a New Approach, *West J Surg* 41, [Feb.] 1933, abstr. THE JOURNAL, Jan. 28, 1933, p. 28, and June 10, 1933, p. 1896.

The "new approach" which I advocated in that paper and have used with good result is one made by removal of a section of the right fifth costal cartilage close to the sternum. A piece of fenestrated flexible rubber tubing of fairly large caliber is then passed through an opening in the pericardium, between the heart and the pericardial wall, obliquely upward and to the left posteriorly, effectively reaching and draining the oblique sinus, where in the fatal cases which come to autopsy the greatest accumulation of fluid is usually found. The great advantages of this procedure are ease of performance, minimum likelihood of injury of the heart muscle, absence of arrhythmia from tube irritation of the apex of the heart, adequate drainage of the oblique sinus, and the fact that drainage can be easily made dependent with slight change of posture of the patient. It is surprisingly satisfactory.

GILBERT COTTAM, M.D., Minneapolis

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

WRITING A HEALTH COLUMN

To the Editor—Our local papers feel that they are unable to take a syndicate service for a health column alone. We have decided that we will appoint one of the members of our county society to write a daily column on health subjects. We feel this is a necessary measure for disseminating accurate medical information to the laity. We would like to know what information and help we could get on this from the American Medical Association and would welcome suggestions on your part.

PAUL MAHONEY, M.D., Little Rock, Ark.

ANSWER—For help in writing a daily health column, which is a very difficult task, the following suggestions are made:

(a) Whoever undertakes the column should subscribe to *Hygeia*. Each month's issue of *Hygeia*, if cleverly used, will suggest enough material for a column a day and leave some over.

(b) The clip sheet of *Hygeia* articles, which is prepared each month, can be had on request. These articles will give suggestions as to the style and length of material suitable for newspaper use. They can be used as is, credited to *Hygeia*, but in any event it seems wise also to point out that *Hygeia* is published by the medical profession and, therefore, the county society is definitely identified with it.

(c) Whoever writes the column should have a complete set of pamphlets of the American Medical Association Bureau of Health and Public Instruction, Bureau of Investigation and Bureau of Medical Economics. They are listed in the catalogue of health publications.

(d) THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, especially the department of Queries and Minor Notes and the department of Book Notices, will furnish many suggestions for the column writer.

(e) There is also a choice from seventy-six topics listed in the pamphlet "Doctors and Public Speaking" which is available from the Bureau of Health and Public Instruction. One of these loan collections will furnish plenty of material, not for one daily column, but for a week.

The following suggestions are offered to column writers:

(a) Write simply using words that can be understood by the least educated and sophisticated of newspaper readers. A good test is to give the material to several children from 12 to 14 years of age. If they can understand it, any adult can who is able to read. Use correct terminology.

(b) Write often of simple things. Cancer, obdurate nervous diseases, peptic ulcers and pernicious anemia afflict few people. It is, pimples, superfluous hair, baldness, headaches and "ouch-mach" are common afflictions.

(c) Write sympathetically, especially when ridiculing false notions that are prevalent in the community.

(d) Write positively when possible. State the facts that can be stated and avoid as much as possible the mention of doubtful or controversial material. There are three kinds of facts for health writing "them as is, them as isn't, them as may be." The first two can be dealt with in simple definite manner. The third must be handled carefully when necessary, avoided when possible.

(e) Do not overemphasize the doctor. When medical attention is necessary, it should be advised without hesitation but direct praise of the doctor is in bad taste in a column sponsored by organized medicine.

(f) Avoid controversial issues, such as antivivisectionism, cultism and quackery. Telling the truth and ignoring controversy is the better educational technic.

(g) Do not attempt to answer questions unless the society can visualize in the future a budget for a constantly increasing volume of correspondence which will require the establishment of source files and numerous journals, books and other reference materials, as well as a growing personnel.

SECOND ATTACK OF GONORRHEA

To the Editor—In February 1936 a man stated that gonorrhea from which he was suffering had been present for seven or eight years. In 1928 he was exposed and went to see a doctor before the start of any discharge. The discharge came on and then for several months he was subjected to intensive treatment with injections foreign proteins and urinary antiseptics. Probably he was over treated. For three or four years he went through numerous hands attempting to clear up his condition. The prostate and epididymis were injected and massage foreign protein and even vasotomy were tried. Most of this time he was in competent hands. In 1931 he had about a dozen negative smears from the prostate so he married. At no time did his wife suffer symptoms suggestive of gonorrhea nor except for an occasional morning drop did the patient himself know anything was amiss. He had been told to ignore the morning drop by a physician after about a year of weekly massage and after his consecutive negative smears. Feb 23 1936 when I first saw the patient he had epididymitis an enlarged soft and tender prostate a smear of which was positive for gonococci and contained a great deal of pus. He was treated with foreign protein and light massage. Two weeks later a profuse discharge appeared. The patient was insistent that reexposure had not occurred. The epididymis at first subsided and flared up again after a month it localized and was opened. Pus positive for gonococci was found. At this time there was also a subacute exacerbation of an old arthritic or neuritic pain in his back and hips which had been present six years before. Since then I have spent my time using urethral instillations for the discharge foreign protein and a mild massage. Today the pus is still positive. The most amazing feature is that examination of his wife three months ago did not reveal any evidence of gonorrhea in her nor at any time has she had suggestive symptoms. Can you tell me what else there is I can do to bring about a cure? Would injections into the prostate through the perineum be advisable? Would any intravenous medication be efficacious? What would be the merit of prolonged heat therapy as is advocated? Please omit name.
M D Illinois

ANSWER—From the evidence presented it may be assumed that the patient was completely cured of the first attack of gonorrhea, which he contracted in 1928, this assumption is based on the facts that the patient had a prolonged course of treatment, a dozen negative smears were obtained from his prostate—and this is probably the most important bit of evidence that he was cured, it being assumed of course that whoever gave the report showing twelve negative smears was in a position to do this and at no time did the patient's wife show evidence that he had infected her. This point is stated so that one may say the patient did not infect his wife and she reinfect him.

With regard to the second attack the correspondent does not give any history of events just prior to Feb 23, 1936. At this time he saw the patient for the first time and found that he had an epididymitis an enlarged, soft and tender prostate, and that smears from the prostate contained pus and gonococci. Gonorrheal infections do not begin this way, therefore the patient had a gonorrheal infection for a week or two or possibly three before he was seen by the correspondent. The fact that the patient insists that reexposure did not occur must be taken with a grain of salt. Records do not indicate the existence of a patient who was cured of gonorrhea, according to the postulates mentioned, who then had a recurrence. The fact that the patient developed arthritis and neuritis can best be explained on the basis of the gonorrheal infection in the prostate.

Injections into the prostate gland through the perineum are definitely contraindicated. Heat therapy in cases of this kind has produced satisfactory results attention should be called to the fact that the treatment is not without its dangers that people have died as a result of prolonged heat therapy in the treatment of gonorrheal infections.

The patient may use a prostatic heater twice a day for fifteen minutes at a time and have mild yet firm massage of the

prostate and vesicles twice a week, to be followed by injections of silver salts into the anterior urethra—mild to be sure 5 per cent mild protein silver or 0.5 per cent strong protein silver. The chances are almost even that the patient has gonococci in both the prostate and the seminal vesicles, and the gonococci reinfect his urethra and when the massage and heat have resulted in eradicating the gonococci and in clearing up the infection in the adnexa, the urethritis will clear up. If however, the urethritis persists and the prostate and vesicles are free of pus one might examine the anterior urethra for infected follicles. It might be well to examine the external urethral orifice for the presence of periurethral passages that may harbor gonococci.

VASOMOTOR NEUROSIS OR RAYNAUDS SYNDROME

To the Editor—A woman aged 45 complains of blanching numbness and the sensation of pins and needles in the two distal phalanges of digits 2 and 4 of the right hand. This first occurred on a hot day last August while the patient was making beds. With cold weather there occurred an increase in frequency of the attacks which may last up to an hour. In the past two months similar blanching has occurred in the distal phalanges of digits 3 and 4 of the left hand. She now has attacks as frequently as three or four times a day. An attack was induced by holding the hands under cold water one minute and lasted about fifteen minutes on the right. The affected parts are blanched and distinctly cold and sensation is almost absent. The physical condition is not other wise remarkable. The blood pressure is 120 systolic 70 diastolic the pulse rate is 72. The deep reflexes are exaggerated and there is a coarse tremor of the outstretched fingers. The menses are unchanged and regular. The patient has consumed close to forty eight bottles of coca cola a week for the past five years. She also smokes twenty cigarettes a day. The blood calcium is 12.20 red blood cells number 4,350,000 the hemoglobin is 75 per cent. I am afraid that she has an early Raynaud's disease but would certainly like to know what there is in coca-cola. I would appreciate any help.

CHARLES KINGSBURY HAMILTON M D New York

ANSWER—The patient has a peripheral vasomotor neurosis and vasospastic phenomena belonging to Raynaud's syndrome. This syndrome occurs in women, is usually symmetrical and almost always involves the upper extremities. Excessive cigarette smoking has been held responsible for causing these symptoms of vasospasm. As far as is known there have been no case reports on peripheral vasomotor neurosis as being due to drinking coca cola. This beverage is supposed to contain a small amount of caffeine, which produces a brightening of the intellectual faculties and an increased capacity for mental and physical work. Caffeine like theobromine and theophylline, is related to the xanthine bodies and is supposed to be a vasodilator. It therefore could not produce vasospasm. It would be simple to determine whether the coca-cola is causing any of these vasospastic symptoms by having the patient quit drinking it. In all probability the spasms will recur. If this is so it is suggested that she stop smoking. Because of the recent onset of the symptoms, the cessation of smoking may be a sufficient enough measure to remedy the abnormal vasomotor impulse and the sympathetic nervous system. Theobromine has been used for years in the treatment of peripheral vasomotor disease.

TRAUMA AND CHARCOT JOINTS

To the Editor—A patient had an accident in a factory and four months later developed Charcot joints. At the time of the accident roentgenograms were taken of the joints which were negative. After four months roentgenograms showed characteristic tabetic changes. Is this man entitled to compensation? Could you cite a case in which it was received?
M D New York

ANSWER—This query brings up a highly controversial subject, one that has been argued in the courts many times, not so often concerning Charcot joints as in cases of tuberculosis and neoplasms developing after injuries. One view is that if a man is working and doing full duty he should be considered in perfect condition unless there is clinical or x-ray evidence to prove that he is not. If he then suffers an accident, following which tuberculosis, a tumor, a Charcot joint or necrosis develops, he is entitled to compensation.

A case cited by Pollosson and Arnulf as quoted on page 284 of Braham and Kahns 'Trauma and Disease, Philadelphia, Lea & Febiger, is as follows. A woman fell with her hands in extension the left hand receiving more weight than the right. There was no immediate difficulty following the accident, but eight days later the thumb was swollen and movements were painful. A month later she entered the hospital, where a diagnosis of tabetic arthropathy of the thumb was made. There were also definite signs of tabes present, but no other symptoms. The conclusion was reached that the localization of the disease in the joint was definitely due to the accident.

The ability of trauma to activate a basic process is generally accepted as its part in localizing a pre-existing process and

to an injured joint or member. The following is quoted from Braham and Kahn. The role of trauma in the production of symptoms of neurosyphilis, or in the modification of the course of the disease, has not been adequately established on a scientific basis. For practical purposes, therefore, one must depend on logical deductions. The one fact that stands out clearly is that neurosyphilis is the result of the invasion of the nervous system by *Spirochaeta pallida*. It seems a logical deduction, generally accepted by the medical profession and given the sanction of judicial opinions, that any type of trauma sufficient to cause definite organic changes in the central nervous system may act as a force in the production of neurosyphilitic symptoms which might not otherwise have appeared, or in accelerating the course of the disease process, or in aggravating symptoms already present, if the individual harbors the spirochete in his body, especially in the central nervous system. Unfortunately, there is no possibility of formulating hard and fast rules to guide one.

PAINS IN THE LEGS IN CHILDREN

To the Editor—A 6½ year old boy has been suffering for the past two years with intermittent attacks of pains in the legs. At the onset which was at the age of 4½ years the attacks occurred approximately every ten days were usually nocturnal with an occasional diurnal attack and were accompanied by rather severe emotional upsets. Recently the periods between attacks seem to be lengthening the child experiences no attacks of pain during the day, and the emotional upsets are either absent or mild. The child has been examined on several occasions by two able orthopedic surgeons who found nothing except (1) moderately tight hamstrings (stretching of these muscles and gentle massage was without results) and (2) a minor degree of flatfoot, which was considered insufficient to produce the type of pain complained of by the patient. Roentgenograms showed no abnormality of the skeleton. Except for a period of vomiting between the ages of 6 months and 3 years which was attributed to forced feeding and anorexia at the present time the history is entirely irrelevant. What etiologic factors should be considered in diagnosing pain of this character and what management is suggested?

M D California

ANSWER—Pain in the legs in a child brings to mind first tuberculosis. The fact that in this case there have been intervals of complete freedom between attacks is against such a diagnosis. Once tuberculosis attacks a joint, although there may be remissions, there is always some residual disability such as stiffness in the mornings and varying degrees of restriction of motion. Also the fact that two orthopedic surgeons have examined the child is important for it is unlikely that they would fail to recognize a tuberculous joint. Legg's disease (Perthes' disease of the hip, or flat head) is seen usually in boys between 5 and 10 years of age and may cause nocturnal discomfort, but there is usually a lump even before the child complains. The x-rays should settle the question as to whether or not such a condition is present. All pain and discomfort may be referred to the knee although the pathologic change is in the hip.

Tight hamstrings indicate that the lesion might be in the knee, but the fact that during two years of observation nothing definite has been determined in spite of careful examination and the fact that emotional upsets have often accompanied the attacks are sufficient to put the examiner on his guard. Neuroses are fairly frequent in children and must be ruled out. Indefinite spells of pain in the joints of children for which no pathologic basis can be found do occur. They alarm the parents and worry the pediatrician and orthopedic surgeon. They were formerly called 'growing pain' but today such a diagnosis is not countenanced. It roentgenogram of the hip and the knee disclose nothing abnormal and the child finds nothing wrong, perhaps the child has a condition earlier called 'growing pains'.

Possible foci of infection such as bad teeth, tonsillitis, etc., should be ruled out. Under the conditions cited it is necessary. The child should be observed. The legs measured as to circumference. The mobility of the joints tested, and roentgenograms of the joints suspected. The child should not be restricted in his activity. If the complaints are established on an organic basis, treatment should be directed to the cause.

DYSMENORRHEA

To the Editor—Kindly give me the physiologic or functional explanations and reasons for both in the following case. A graduate nurse aged 26 married 2 years without pregnancy or the use of contraceptives has had dysmenorrhea with a heavy menstrual flow since having scarlet fever at 20 and has such painfully tender breasts for a week before menstruation that her clothes pressing on them bother her. She started menses at 12 years. She is thin but healthy in appearance is 5 feet 2 inches (158 cm) in height weighs 90 pounds (41 kg) and is very active physically and mentally. She thought when she was up a more sedentary life that her condition would improve. It did not and she was given ovarian tablets before her last menstrual period hoping that stimulating the ovarian action would possibly relieve the breast pain. It seemed to do so, but after flowing some twenty-four hours she was taken with severe flooding while sitting quiet. Physical examination revealed normal sized genitalia with no tumor growths, tenderness or adhesions. There was no tenderness in the region of the appendix. There were no varicose veins of the broad ligaments. The thyroid was not enlarged. The pulse was normal in rate and regularity. She can usually feel a pain in the region of one or the other ovaries at the time of ovulation. The bowel movements are regular. She has been able to be on her feet through the menstrual period until the last six months and would probably not have gone to a doctor if she had not seemed to be getting worse. She has had no venereal infection and was always well and strong except as stated.

M D Minnesota

ANSWER—Presumably the scarlet fever produced some disturbance in the internal genitalia which led to the dysmenorrhea and the increased menstrual flow. Since no gland product stimulates its parent gland, the administration of ovarian tablets to stimulate ovarian action was illogical. Furthermore, there is no reason to stimulate ovarian activity in this case because there may already be excessive production of estrogen. Parenthetically it may be added that desiccated ovarian substance is practically inert.

Since the patient is underweight, it is advisable to have her gain a few pounds. The pain that occurs at the menses and the profuse bleeding may both be due to excessive amounts of estrogen. This condition may be overcome in some cases by the administration of progesterone or progestin. One international unit of progestin should be given hypodermically every second day, beginning at about the middle of the intermenstrual period or when the patient experiences pain at ovulation and continued until the actual flow begins. It may be advisable to precede the use of progestin by a dilation and curettement. This operation may relieve the dysmenorrhea at least temporarily. More important still, it may permit a definite diagnosis of the uterine endometrium, such as hyperplasia, and it will almost certainly reduce the amount of menstrual bleeding at least for a few months. If relief is obtained by the dilation and curettement, the use of progestin should be postponed unless the histologic examination of the endometrium definitely shows hyperplasia of the endometrium.

STERILITY

To the Editor—A woman aged 27 married ten months in good general health desirous of having children fails to become pregnant. The menstrual periods are regular there are slight menstrual cramps. The period occurs every thirty days. She had delayed menstruation two months after marriage—fourteen days late—and then passed clots of blood with cramps apparently an abortion. She had a previous operation (Aug 25 1930) for appendicitis. The pelvis, which was explored at that time showed a very marked retroflexion, a round ligament purse string operation was done to separate the uterus, the right ovary was slightly cystic and was treated. Pelvic examination at present reveals the uterus still retroflexed. What are the chances of pregnancy in cases like this of retroflexion? What procedures should be instituted to promote pregnancy? The husband's spermatozoa are apparently normal. Would the supposed abortion be a cause of her sterility?

M D Pennsylvania

ANSWER—Many women who have had appendicitis before marriage are sterile but in a large proportion of them the sterility can be overcome. Uncomplicated spontaneous abortion rarely is followed by sterility. Retroflexion of the uterus by itself is not often the cause of sterility, but an easy way to determine this for the patient in question is to elevate the uterus and insert a pessary into the vagina. The pessary should be left in the vagina for at least three months. The patient could be instructed to be sure to have intercourse during the middle third of each menstrual cycle. If no pregnancy follows, the use of a vaginal pessary. A Rubin test should be performed. Gas passes through the tubes when the uterus is retroflexed. If the position of the uterus cannot be blamed for the sterility, there is obstruction to the gas when the uterus is retroflexed. The test should be repeated with the uterus elevated. If gas passes through the tubes when the uterus is elevated but not when it is retroflexed the patient should continue to wear a vaginal pessary. A suspension operation may be considered if the tubes are impermeable to gas iodized oil should be used.

be injected into the uterus to determine the site of the obstructions. It is conceivable, and it has happened, that in performing a suspension operation the fallopian tubes were mistaken for the round ligaments. Repeated attacks of appendicitis not infrequently result in the closure of the fallopian tubes. Whether or not to operate in the presence of impermeable tubes is a difficult question to decide. The results are not very promising. For a review of the literature on this subject see, J. P. Greenhill's article on 'Evaluation of Salpingostomy and Tubal Implantation for the Treatment of Sterility' (*Am J Obst & Gynec* 33:39 [Jan] 1937).

POSSIBLE CANCER OF BREAST

To the Editor—A woman aged 37 a nullipara was operated on five years ago and the left ovary (dermoid cyst) with the left tube a part of the right ovary (cystic degeneration) a part of the right salpinx and eight small intramural myomas of the uterus were removed. The monthly cycle of menstruation is twenty six days and the duration two and one-half days. About two weeks ago she experienced a feeling of fullness in the left breast and pain in the nipple and in the higher part of the breast at the edge of the pectoralis major muscle. By pressure on the nipple of the left breast there appears a gray greenish liquid by pressure on the right nipple there appears a gray milky liquid. No tumor is to be felt. High in the armpit on both sides is a small gland. A numb feeling is in the left arm. I thought the pain was in connection with diminished ovary substance and gave progynon B. Can it be cancer?

M. D. Dutch West Indies

ANSWER—From the description given there is no evidence that the patient has cancer of the breast. It is much more probable that the patient has some infection of the ducts of the breast, which gives rise to the fluid that can be expressed from the nipple. It is doubtful that endocrine therapy will do the patient any good. Warm moist local applications should be made to both breasts and if necessary, the secretion from the duct removed by a breast pump. Should any thickening or lumps appear, it may be necessary to incise the breast and give free drainage to any infected area. If such incision becomes necessary it may be wise to remove some tissue place it promptly in strong alcohol to fix it, and have a microscopic examination made of it. The type of inflammatory reaction could then be determined and might offer some suggestion for further treatment.

GANGLION OF THE WRIST

To the Editor—A colored man aged 33 stated that while packing aprons in a wringer in a laundry where he worked he twisted his left hand and wrist. About five minutes later a fellow worker called the patient's attention to a swelling on the ventral aspect of the affected wrist. The patient stated that he had never had any such swellings before. It was a soft cystic mass not attached to the skin. There was a distinct pulsation over the mass but this was evidently from overlying vessels. There is a history of the patient's having been treated for syphilis several years ago. A Wassermann reaction taken now is negative. Aspiration yielded a thick mucinous fluid obtainable only through a large bore needle. A diagnosis of ganglion was made. The question here is one of etiology. What relationship had the injury to the development of the cyst? Is it of traumatic origin? Was the trauma only a partial contributing factor in its production?

M. D. New York

ANSWER—Ganglion of the dorsum of the wrist results from a mucinous degeneration of the joint capsule or of the tendon sheaths. These cysts may be single or multilocular in character involving small or large areas. Their relation to trauma is frequently indefinite although they are often encountered in persons who use this joint excessively. The diagnosis may be made by the typical location in relation to tendon sheaths or joints, by the firm but cystic consistency and by transillumination. The recovery of thick, mucinous fluid is confirmatory. They should be differentiated from other forms of synovial disturbances, especially tuberculous tenosynovitis, xanthoma of the tendon sheath and arborescent lipoma.

The tumor mass mentioned was probably of long standing for it was first noticed by his fellow worker and not by himself, as probably would have been the case in a sudden swelling which undoubtedly would have been accompanied by some degree of pain. Symptomless ganglions are frequently present over long periods without their presence having been noted by the patient. The time elapsing between the reported injury and the recovery of thick mucinous fluid is important. The presence of such fluid suggests that the ganglion was of long standing, for otherwise the fluid would have been more serous in character. Any causative relation between the ganglion and the injury sustained may be questioned. At best such an injury might be a minor contributing factor first by revealing some dysfunction of the joint and secondly by attracting the patient's attention to the abnormal contour of the wrist.

LOCAL ANESTHETIC AND SKIN INJURY

To the Editor—Has there been anything in the literature relative to harmful effects of injections of procaine hydrochloride 1 per cent in the skin under high pressure? On various occasions I have had skin edges fall apart about the sixth or seventh day without any evidence of infection. Could it possibly be due to the pressure and poisonous effects of procaine in the skin?

W. L. Brown, M.D., El Paso, Texas

ANSWER—There are references in the literature to the untoward effect of injection of procaine hydrochloride on the skin. However, it is highly improbable that healthy tissue will not tolerate 1 per cent procaine solution in excessive amount unless injected so that the skin is separated from its lymph supply and absorption is slow. The more likely explanation, if the untoward result can be laid to the local anesthetic is that trauma was caused by the needle being passed through the tissue more often than was necessary. It is well to minimize the number of thrusts of the needle through tissue when depositing the anesthetic solution.

TOXICITY OF FLUORIDES

To the Editor—What are the toxic properties if any of an aqueous solution of sodium fluoride used as a spray on clothing blankets or rugs for the prevention of moths? I am told that there are commercial products in which fluoride is incorporated in a colorless dye which is relatively permanent in its moth proofing effect and without any possible toxic effects. Any information on such compounds will be appreciated.

R. Barry Bigelow, M.D., Boston

ANSWER—Sodium aluminum silicofluoride, which is a water soluble substance used in the moth-proofing of fabrics and furs, is not known to be toxic in the amount used for this purpose. If it is toxic, this fact is not well established and the presumption is that at least it is far less toxic than ordinary sodium fluoride. Of various common compounds of fluorine, sodium fluoride is probably the most toxic. In concentrations of as little as one part per million of water in drinking water supplies mottled enamel of the teeth of children has occurred. In adults, as little as five parts per million of fluorine has led to a severe degree of mottled enamel. In animal experiments, such small quantities of sodium fluoride as 1 mg per kilogram of body weight has led to ill results. However for man the proportionate threshold of harm is apparently higher, from 6 to 10 Gm of sodium fluoride may be required to bring about fatality. There is some reason to believe that the commoner forms of fluorine ingested are transformed to calcium fluoride, which is said to be less toxic than the corresponding sodium compound. From weak solutions of sodium fluoride (1 or 2 per cent) mucous membranes may be damaged, but higher concentrations are required to damage the skin. It must also be remembered that some of the commercial moth proofing fluoride solutions may contain other ingredients that might be toxic.

BLOOD TESTS FOR NONPATERNITY

To the Editor—Can you inform me to what extent blood grouping is used in court procedures in legally establishing the nonpaternity of a child. I have at present a case in which the mother and the alleged father are in group O and the child is in group A. Under those circumstances would it be possible for the alleged father to be the father of the child?

Charles L. Sherman, M.D., Iverne, Minn.

ANSWER—Blood grouping tests have been used extensively abroad and to a certain extent in this country in court procedures for the purpose of establishing the nonpaternity of a child. As far as our country is concerned the tests have been most frequently used in New York State, but they have also been applied in Connecticut, New Jersey, Pennsylvania, Wisconsin, Maryland and California. Laws giving courts the authority to compel persons involved in paternity proceedings to submit to such tests have been passed in New York State and Wisconsin, and bills are pending before the legislatures in

New Jersey, California and Montana. Judicial notice of the value of the tests has been accorded by a number of courts, and the following reported decisions are representative:

Beuschel v Manowitz (1934), 271 N Y Supp 277
State v Damm (1936), 266 North Western Reporter, 667
Aias v Kalensnikoff (1937), 67 Pacific Reporter, 1059

A detailed discussion of this entire question appears in Report of the Committee on Medicolegal Blood Grouping Tests (*THE JOURNAL*, June 19, 1937, p 2138). Also see the article by S H Britt "Blood Grouping Tests and the Law" (*Minnesota Law Review* 21 671, 1937).

The case cited, in which the mother and the alleged father both belong to group O and the child to group A, does not satisfy the laws of inheritance of the blood groups. Hence one or the other (or both) of the supposed parents is not the real parent of the child. If there is no reason to doubt the maternity of the child, the accused man cannot possibly be the father of the child.

RESIDUAL URINE AFTER TRANSURETHRAL RESECTION

To the Editor—I have a patient, aged 55 who had a punch operation for prostatitis sixteen months ago. Since his operation he has been unable to empty the bladder completely. Following urination he has from 4 ounces to a pint (from 120 to 475 cc) of retention urine seepage at night. Robert's test shows much pus and a trace of albumin. There is no obstruction, a large catheter is passed without force. Please advise prognosis and treatment to improve the condition.

H A SIMRELL M D Stockton, Mo

ANSWER—There are many reasons for the occurrence of residual urine following transurethral resection, but from the data given a definite cause cannot be stated. Generally the chief reason is incomplete removal of obstructing tissue. The expert in transurethral prostatic resection will find it necessary to reoperate on about 10 per cent of his patients in the immediate postoperative period to eliminate the residual urine. During the next five years he will have to reoperate on about 5 per cent of his patients because of recurrence of symptoms. Rarely transurethral resection is done when the residual urine is due to a neurogenic bladder disturbance rather than prostatic obstruction. Such an operation cannot be expected to relieve the residual urine. Probably the seepage in this case is overflow incontinence, but this factor should be considered if further surgery is advised. A diagnosis of prostatic obstruction cannot be made by the passage of a catheter and this patient should have a careful cystoscopic examination. It has been found that the common place for tissue to be left behind is in the anterior portion of the lateral lobes. Unless this area is carefully inspected at the cystoscopic examination, the obstructing tissue will be overlooked. Should there be no obstructing prostatic tissue found at cystoscopic examination, the treatment should consist of an attempt to control the urinary infection by lavage of the bladder and acidification of the urine with from 4 to 5 Gm of ammonium nitrate daily combined with either mandelic acid or methenamine. Sterilization of the urine and eradication of the pyuria can hardly be expected with this amount of residual urine.

SHUFFLE FOOT

To the Editor—I would appreciate your sending me what information you may have on a nerve injury producing the shaking of the foot and knee popularly known as shuffle foot.

M D Illinois

ANSWER—We are not acquainted with any condition popularly known as "shuffle foot."

In the spastic or hemiplegic gait the leg is stiff and the affected foot is shuffled or, better scraped forward usually with circumduction. With bilateral spastic paralysis of the lower extremities the circumducting scraping motion of both legs produces a crossed progression or scissors gait. Such spastic paralysis is caused by a lesion of the pyramidal tract at some point in its course between the motor cortex and the anterior horn cells. In cerebral arterio sclerosis or frontal rigidity the patient may progress with very short shuffling steps.

Paralysis of the common peroneal nerve at the knee joint dorsiflexors of the foot results in a gait in which it is necessary for the patient to lift the foot high enough when walking in order to clear the heel. When the foot is moved forward (stepped forward) the patient usually lifts too high from the ground.

In tabes dorsalis due to degeneration of the posterior horns, the gait is unsteady, jerky, usually lifted too high from the ground. The patient must look at his feet when walking. In vision, he is unable either to walk

TREATMENT OF BURNING SENSATION AFTER ROENTGEN THERAPY

To the Editor—A white woman aged 72 had a radical operation for both breasts in 1928 for carcinoma. Two years ago small nodules began to appear in the scar and surrounding skin. Biopsy showed that they were malignant. During the past two years she has had intensive high voltage roentgen therapy. In fact the roentgenologist refuses to give her more. These nodules are increasing rapidly and are beginning to break down. At times the burning is intense and she does not care to take any more. Please omit name.

M D Missouri

ANSWER—A good preparation to put on an area in which the skin is not broken but which has been thoroughly irradiated and is itching or burning, consists of phenol 3 Gm (48 grains), zinc oxide 10 Gm (2½ drachms), glycerin 40 drops and sufficient solution of calcium hydroxide to make 120 cc. The bottle should be shaken and some of the fluid poured on absorbent cotton and dabbed on the irritated areas.

As an alternative to this mixture one may use the official solution of aluminum acetate for a day or two.

If the skin is broken and these preparations are too irritating a good ointment which protects the ulcerated areas from air and also has some analgesic effect is one made up of phenol 0.2 Gm (3 grains), oil of eucalyptus 2 cc (one half drachm), castor oil 8 cc (2 drachms) and sufficient petrolatum to make 30 Gm (1 ounce). In addition, small quantities of codeine can be administered in capsule, so that the patient does not appreciate that she is taking an opiate. A very useful formula is a capsule containing 0.2 Gm (3 grains) of acetylsalicylic acid 0.13 Gm (2 grains) of acetphenetidin and 0.03 Gm (one half grain) of caffeine citrate, and if this does not hold the patient, substitute an 0.008 Gm (one eighth grain) of codeine for the caffeine citrate. Then this can be alternated with bromide.

WASSERMANN TEST OF UMBILICAL CORD BLOOD

To the Editor—Please inform me as to the reliability of cord Wassermann tests as indicating congenital syphilis. In a case in which there is a positive cord Wassermann reaction, a positive Wassermann reaction on the mother and a negative Wassermann and Kahn reaction on the baby's blood, should antisyphilitic treatment be given the baby when there are no clinical signs of syphilis? In a case in which the mother has had no history of syphilis and has had three negative Wassermann reactions but a cord Wassermann reaction is obtained on the baby whereas the baby's blood Wassermann reaction is negative, should the cord Wassermann report be ignored?

M D, Rhode Island

ANSWER—A Wassermann test done on the serum obtained from the umbilical cord at birth is essentially a Wassermann test of the mother. Likewise a Wassermann test done on blood drawn from the baby during the first few weeks of life is not a true index that the child does or does not have syphilis. A positive test obtained at the second week of life may spontaneously become negative by the sixth week of the baby's life. In the case cited it would accordingly seem advisable to repeat the test several times at intervals of two weeks and thereafter according to the reports and the clinical development. If the test remains negative for six months, treatment for the child is not necessary.

The same answer is applicable to the second question, in that repeated tests of the child's blood are more authoritative than the test done on the cord blood serum.

VITAMIN B IN DEAFNESS

To the Editor—A man aged 35, recently asked my opinion concerning vitamin B in deafness. He tells me that his deafness is due to a catarrhal condition. He has consulted several otologists and has spent two years in Texas. Could you tell me the results of vitamin B in deafness?

M D Illinois

ANSWER—The use of vitamin B₁ in the treatment of deafness is in the experimental stage. The rationale of vitamin therapy is based on the assumption that some forms of deafness are due entirely or partially to disease of the auditory nerve and that vitamin B₁ plays an important part in the treatment of some forms of neuritis.

Although encouraging response has been noted in some ear clinics, no published reports are available as yet which can permit a clinical evaluation of this therapy. For experimental purposes the daily dose of from 1000 to 2000 international units of natural or synthetic vitamin B₁ by mouth has been arbitrarily selected. Suitable patients should be kept on this daily dose for from four to twelve weeks depending on the duration of the auditory neuritis present. When improvement is noted, the administration of vitamin B₁ may be continued for a longer period.

MEINICKE TEST FOR SYPHILIS

To the Editor—What is the value of Dr Meinicke's antigen which is advertised as a turbidity test and a microreaction? The advertisement states that this test has been endorsed by the Pasteur Institute the University of Vienna and a number of other authorities abroad and in this country. I am in need of a simplified method for the diagnosis of syphilis and would appreciate your evaluation of this test as to reliability compared with the Wassermann and Kahn tests.

SOLOMON WEISS M D Sisseton S D

ANSWER.—At the Copenhagen conference of the League of Nations Health Organization, held in 1928, Dr Meinicke demonstrated his turbidity test, but the results obtained with this test even in his own hands were so poor that he soon abandoned it and later came out with a clarification test, which has since undergone several modifications. There is no excuse for a method which as far back as 1928 proved unreliable.

UNDESCENDED TESTIS

To the Editor—I have as a patient a boy of 13 who was of premature birth. He is somewhat backward in his general mental development and also slightly in his physical development. He has a right scrotal hernia and a right undescended testicle. The hernia can be readily reduced and on straining the right testicle can be felt over the pubic symphysis but cannot be readily palpated unless the boy strains and apparently is undeveloped. What is the accepted treatment for a combination of this sort?

M D Illinois

ANSWER.—The boy should have the testicle brought down into the scrotum and the hernia corrected. This is not the type of case that one could expect to correct by any other method of treatment.

AGE OF MARRIAGE CONVENTION

To the Editor—It seems to be the custom for a man to wed a woman of the same age or several years younger than he. Also he is usually advised not to marry a woman five years older. Is there a medical reason for this? Does the potency of healthy women last as long as that of healthy men? What percentage of divorces actually are the direct or indirect result of sexual incompatibility? Can you refer me to a book which discusses the essentials of a happy married life including other phases beside sexual such as emotions, intellect, occupation and sanity or mental illness?

M D Oklahoma

ANSWER.—As a rule women mature much earlier than men and lose their potency much earlier. As a rule, women do not care for sexual intercourse after 50, whereas men at this age are at about the height of their sexual life and continue to have desire for from ten to twenty years more. Sensible women past 50 will not object to their husband's inclination, although they often do not enjoy the act.

"A Research in Marriage" by G V Hamilton and "What Is Wrong with Marriage?" by Hamilton and Macgowan, both published by Albert & Charles Boni, Inc., New York, give statistics on all the other questions mentioned.

SYPHILIS AND PREGNANCY HORMONES

To the Editor—Are there any references in the literature to the treatment of syphilis with pregnancy hormones alone or in conjunction with the heavy metals?

LOUIS J WEINSTEIN M D Denver

ANSWER.—There seems to be no report of the treatment of syphilis in human beings with pregnancy hormones. There are two articles on syphilis in animals with somewhat divergent conclusions.

Kemp J E. The Effect of Pregnancy and of Female Sex Hormones in Modifying the Course of Syphilis in Experimental Animals. *Infect Dis* 60 32 (Jan Feb) 1937.

Frazier C N, Mu J W and Hu C K. Influence of Estrogenic Substance upon Experimental Syphilis of the Adult Male Rabbit. *Proc Soc Exper Biol & Med* 33 65 (Oct) 1935.

In Kemp's article will be found other references of interest.

PSYCHOSIS FOLLOWING ATROPINE IN EYE

To the Editor—Can you send me any information regarding psychosis due to instillation of atropine for refraction of the eyes? Information available here does not reveal any cases in children and only one case in an adult.

L L BARROW M D New York

ANSWER.—As far as a search of the literature reveals, there are no recorded cases of psychosis following the use of atropine for refraction. Undoubtedly the condition does occur in children but it is only temporary. The psychoses and hallucinations due to atropine appear in the advanced stage of the poisoning and disappear spontaneously within a few hours after the use of the drug has been stopped.

Book Notices

Russian Medicine By W Horsley Gantt M D Johns Hopkins University School of Medicine
Clio Medica A Series of Primers on the History of Medicine Edited by E B Krumbhaar M D Cloth Price \$2.50 Pp 214 with 12 illustrations New York Paul B Hoeber Inc 1937

This little volume is another of the handbooks of medical history published under the general title of Clio Medica. The author has published many of the chapters as individual essays in the *British Medical Journal*. He emphasizes in the preface his friendship with John Dos Passos, which inclines the informed reader very early to the expectancy of finding an approval in this book of socialized medicine. That expectancy is confirmed in the final chapter of this history, which is entitled "Soviet Medicine." In this chapter the author indicates, however, that the social insurance scheme has not been wholly of benefit. Thus he says "In thus replacing the private by a governmental doctor and providing free treatment for the employees, the state, in spite of remarkable progress, has attempted a larger task than it has been able at present to solve adequately. Doctors and medical personnel are tired, overworked and often indifferent, the system is slow and cumbersome, so that the patient is frequently 'well or dead' before his turn comes for the sanatorium. This condition of the doctors is improving with the increased numbers being turned out by the medical schools." Incidentally, recent visitors to Russia have pointed out that some of the doctors turned out by the hastily developed medical schools have hardly the education that we would give in this country to a well trained nurse. If one reads Dr Gantt's account for the facts that it contains one finds it rather hard to justify his interest in the 'sincere and determined attempt to create a new socialized medicine, in strict adaptation to the needs of the public, backed by all of the political and economic forces of the Soviet state.

Sleep Characteristics How They Vary and React to Changing Conditions in the Group and the Individual By N Kleitman F J Mullin N R Cooperman and S Titebaum The Department of Physiology of the University of Chicago Cloth Price \$1 Pp 87 Chicago University of Chicago Press 1937

There was a time when a physiologist might catch a few frogs, take a piece of wire and a bit of rubber borrow or build a kymograph, and with these and similar modest materials undertake to clarify fundamental problems of the action of the heart or the behavior of muscle but now judging by this little brochure, methods, apparatus and problems have changed. The present authors secured thirty-six human subjects gave them directions and printed forms for recording data fitted their beds with a device to record the motions of the sleeper—it is called a work adder—and proceeded to study the effects of drugs and foods on the characteristics of sleep. The data were then transferred to punch cards tabulated with the aid of a Hollerith census machine and the results treated by statistical methods. Among the conclusions so obtained appears the startling pronouncement (which however the writer of advertising copy seem to have known in advance) that Ovaltine is the only material which when taken at bedtime increases the percentage of morning feeling well rested. The record of waking up feeling refreshed on 52 per cent of mornings after taking no bedtime snack of any kind compared with 14 per cent of the mornings after taking 14 Gt. Common sense should dictate even the statistical methods employed in the differences or more extensive tests desirable before the authors could

This little book is apparently a collection of lectures delivered to young girls. The approach is along psychologic lines and there is a good effort to coordinate views on sex hygiene with mental hygiene. The book, however, is noticeably deficient in physiologic instruction. There are no diagrams and no bare discussions of the mechanism of reproduction, the glandular control of the sexual organs, the meaning of menstruation and other physiologic problems. The author repeatedly uses terms such as fertilization and ovum without definitions. It may be that the English girls of this age find the book informative, but it appears to offer too little factual material to satisfy the girls of this age group in America. In addition there is an evasive, apologetic manner in the book which was frequent in earlier American teachings but is outmoded at this time. In the description of childbirth, the pain attending this phenomenon is mentioned three times in two short paragraphs, and in spite of the fact that little description is given, the author finds it necessary to mention that the mother may be torn. This may open the presentation to the criticism that it is too frightening for young girls. Moreover, in the one paragraph referring to marriage the author finds it necessary to associate briefly the idea of physical marital relationship with animal experiences and then rushes on to reinforce the shamefulness of sex relations by discussing prostitutes. This appears to be an unfortunate and unnecessary association. On the psychologic side the author gives a number of good suggestions as to the way to get along with other people and the necessity for entering broadly into social relationships.

La chirurgie de la douleur Par René Leriche professeur de clinique chirurgicale à la Faculté de médecine de Strasbourg Paper Price 65 francs Pp 428 with 13 illustrations Paris Masson & Cie 1937

This volume is based on a course of twenty lectures delivered at the College of France. The author discusses the nature of pain and its physiology. The general plan of surgery for the relief of pain is described. Leriche's aim is to clarify several aspects of the problem of pain in which, for the past several years, surgery has given us an entirely new conception. The painful conditions the surgical therapy of which is discussed include trigeminal neuralgia, painful neuromas, causalgia, painful amputation stumps, painful vasoconstrictions and Raynaud's disease, arteritis, angina pectoris, painful scars and inoperable cancers. The book is well indexed and printed. Leriche is an earnest student and experienced teacher of this subject and his voice is that of authority. The book is of value to all interested in this subject.

Synopsis of Gynecology Based on the Textbook Diseases of Women By Harry Sturgeon Crossen M D F A C S Gynecologist to the Barnes Hospital St Louis Maternity Hospital St Louis and Robert James Crossen M D Assistant Professor of Clinical Gynecology and Obstetrics Washington University School of Medicine St Louis Second edition Cloth Price \$3 Pp 247 with 106 illustrations St Louis C V Mosby Company 1937

This small book was first produced in 1930 and is based on Crossen's "Diseases of Women." Through twenty chapters it follows the sequence of subjects in the larger book. The synopsis is printed in fine type, which makes free reading somewhat difficult but permits the authors to include in a pocket volume an unbelievable amount of valuable information, well arranged and well tabulated. Endocrinology is especially summarized, and this is indeed a difficult task to do successfully. The authors' discussion of the several types of vaginitis is well done and is only one of several indications that the work has been brought down to date. The diagnosis of cancer and the effects of radium on tissues are comprehensively covered in relatively few words. The chapters on menstrual disturbances and disorders of other organs in relation to gynecology are especially good, though concise, the chapter on venereal sexual disturbances began well but appeared finally to be less

ing in many essential details, owing obviously to its abbreviation. Details of surgical procedures are purposely omitted and would have been out of place if included. The illustrations are simple but effective line drawings, with a few reproductions of those in the parent book or from other works. As an explanation of why one would prepare a synopsis of a successful textbook, the authors state that this type of book is intended primarily for students who do not expect to practice gynecology extensively but who may often have need for a small reference book. It should be ideal for them, and likewise helpful for quick reference to those who intend to undertake at least a considerable amount of gynecologic practice.

American and Canadian Hospitals. A Reference Book of Historical Statistical and Other Information Regarding the Hospitals and Related Institutions of the United States and Possessions and the Dominion of Canada. Published under the Supervision of American Hospital Association Catholic Hospital Assn of the United States and Canada American Protestant Hospital Association Canadian Hospital Council. Second edition. Cloth. Price \$10. Pp 1448. Chicago: Physicians Record Company, 1937.

This is a valuable reference book of information regarding hospitals and related institutions of the United States, its possessions, and the Dominion of Canada. The main section is a list of the hospitals that are recognized in the American Medical Association's Register of Hospitals. It gives information regarding each of these institutions that has not been compiled elsewhere, especially history, organization and special services provided. The orderly arrangement facilitates finding the desired data. Other sections are equally informative. These include (1) a description of each of the fifty-six medical and hospital organizations that are active in the hospital field, (2) state, regional and local hospital associations and councils and associations of superintendents, and (3) standards for hospitals, including those of the American College of Surgeons, the American Medical Association and other standardizing agencies.

Physiologie du système lymphatique "Formation de la lymphe circulation lymphatique normale et pathologique." Par H. Rouvière, professeur d'anatomie à la Faculté de médecine de Paris et G. Valette, pharmacien des hôpitaux de Paris. Paper. Price 45 francs. Pp 160 with 33 illustrations. Paris: Masson & Cie, 1937.

This work is at once a textbook on lymphatic physiology and a review of current progress. The authors have given both a simplified discussion and an analysis of the works of a representative group of investigators. The text is simple and concise and easily readable even with an elementary knowledge of French. The first seven chapters deal with the normal physiology and anatomy of the lymphatic system, the composition of lymph and tissue fluid or "le liquide lacunaire," the physical and chemical factors modifying the production, composition and movement of these fluids, and finally the influence of the various classes of lymphagogues. This discussion is carried over into the second part of the book with applications to pathologic disorders such as regeneration of lymph nodes after extirpation, establishment of collateral circulation after interruption, and finally pressure edema and elephantiasis. Evidence on controversial points is well balanced and impartially presented, although the authors do not hesitate to advance their personal views on such points. The anatomic and histologic drawings are especially well done.

Interim Report of the Inter-Departmental Committee on the Rehabilitation of Persons Injured by Accidents. Home Office, Ministry of Health and Scottish Office. Paper. Price 4d. Pp 20. London: His Majesty's Stationery Office, 1937.

It is a peculiarity of the English compensation legislation that it provides only for cash indemnities and not for medical care. The result of this has been to throw most of the medical care into the voluntary and governmental hospitals. In the course of 1935 the numbers of new fracture cases treated in the voluntary hospitals which supplied figures were 132,702 treated as outpatients only and 45,478 as inpatients, or about 75 and 25 per cent respectively of the total number treated; the numbers treated in the municipal hospitals were 9,372 as outpatients only and 14,180 as inpatients. Not all these were industrial cases but a large percentage of them were. As a result of this situation the Inter-Departmental Committee prepared a scheme for the organization of fracture clinics on the basis of the general principles recommended in the British

Medical Association's Report." Since the surgeons in the voluntary and governmental hospitals are not permitted to charge for their services, practically all of this work was done without remuneration from patients or employers. It is proposed, however, that the surgeon who works in the "fracture clinics" should "receive some honorarium for his services." It is figured that "a large clinic in a city hospital of 500 to 1,000 beds dealing with 2,000 to 2,500 fractures per annum" would require one surgeon in charge, two whole time assistants, one resident radiographer, two resident house surgeons, one stenographer and one record clerk. It is proposed that the total cost of such a staff per annum would be £1,650, or a little over \$8,000. In spite of the use of the word "rehabilitation" in the title, there seems to be nothing in the report to indicate that rehabilitation, as it is understood in the United States, consisting of orthopedic treatment, education, training and placement, is to form any part of the new scheme. Appendices on the principles of modern fracture treatment, routine of a fracture department, planning of the clinic, and equipment are attached to the report.

Out of My Life and Work. By August Forel. Translation of Rückblick auf mein Leben by Bernard Miall. Cloth. Price \$3.75. Pp 352 with 8 illustrations. New York: W. W. Norton & Company, 1937.

Throughout this autobiography run the recurrent strains of the writer's interests in ants, hypnotism and total abstinence. Born and living most of his life in French speaking Switzerland, Forel was among the first to introduce more humane treatment of mental patients. His life was a strange mixture of conflicting emotions, understandable perhaps from his frank description of his ancestors and his shy and lonely childhood. Early in his professional life a friend had demanded of another doctor the truth as to his condition. He was told that he had only a short time to live and Forel, in spite of what he calls his truthful upbringing, thus learned, he says, the value of the occasional "ethical lie." A strain of naivete is illustrated in innumerable sections of the book and adds much to the charm. In one place he says, "Since then I have realized more and more clearly every year what an inestimable service the girl with whom I was in love in 1879 did me by rejecting my addresses. She herself married a wealthy numskull and had no children." In places the author's investigations on ants, his contacts with such persons as Lombroso, his political difficulties and his connections with total abstinence are of considerable scientific or historical significance. The type of life recorded seems far removed from any which we know today in this country, but as such it possesses a charm different from that of most of the recent biographies and autobiographies.

Immortal Names and Other Poems. By T. Wilson Parry, M.A., M.D., Fellow of the Society of Antiquaries and of the Geological Society. Cloth. Price 5s. Pp 122. London: Ulster Press, 1937.

Many of the poems in this book were printed in the *Cambridge University Society Magazine* and in the *St. George's Hospital Gazette*. The poems of the author are collected under various headings, including "Immortal Names," "Travel Sketches," "The Quest Eternal," "Miscellaneous" and "Trifles." The poems are mostly in sonnet form and practically all have a definite medical interest. The author is an active practitioner of medicine and also an authority on prehistoric trephining. The book is beautifully printed. The poems present a considerable inequality. Those dealing with the immortal names are of an exceedingly high order. Especially interesting, however, is one called "The Family Doctor—A.D. 2028," which begins

The General Practitioner is now alas no more
Gone are his lamp and speaking tube the plate upon his door
By Britain he was once beloved and wanted in his way
But constant Socialistic schemes have spoilt his kingly sway

Another verse says

A Minister of Health conceived a vast and crazy plan—
That Britons all should be upon the Panel to a man
So now the Art of Healing has been shifted to the State
Folks have to do as they are bid—A.D. 2028!

Fortunately the next six verses are succeeded by a concluding verse which reads

The Public will be satisfied if not they will protest
The Government pulls many strings and oftentimes not the best
But Parliaments may rise and fall it is their willful way
The General Practitioner has now returned to stay!

Handbook of Hygiene for Students and Practitioners of Medicine By Joseph W. Bigger M.D. Sc.D. F.R.C.P. Professor of Bacteriology and Preventive Medicine University of Dublin Cloth Price \$4 Pp 405 with 18 illustrations Baltimore William Wood & Company 1937

This small handbook of hygiene covers an almost unbelievable amount of ground. Vital statistics, insect-borne diseases, parasitic worms, occupational hygiene, poisonous gases, personal hygiene and the assessment of normal health are all included with the other subjects more commonly discussed in a short textbook of hygiene. The discussions are brief, as they needs must be, but on the whole the material is well selected and accurate. A sentence on page 107 is especially interesting in view of the recent furor about poliomyelitis. The sentence reads "Epidemics (of poliomyelitis) rarely occur in cities." This statement does not appear to apply in this country but may represent a difference in the biology of the disease in Ireland. There are no references to the literature in this book, but for the purpose of an elementary introduction to the subject it would be hard to find anything so inclusive, either more simply written or more condensed. For this purpose it should be of considerable use to teachers and students.

Précis de médecine coloniale. Par Ch. Joyeux professeur de parasitologie à la Faculté de médecine de Marseille et A. Sicé professeur à l'École d'application du corps de santé colonial de Marseille. Second édition. Cloth Price 170 francs Pp 1250 with 240 illustrations Paris Masson & Cie 1937

This work on colonial or tropical medicine is divided into three parts. In the first the diseases are grouped according to the organs affected: the digestive tract, respiratory system, blood and lymphatic systems, and so on; in the second the febrile maladies are considered, and in the third are grouped certain general conditions ranging from rabies to venomous bites and seasickness. Such a classification leads to many inconsistencies, as, for example, the separation of diseases the etiologic agents of which are closely related. In general the French colonial medical worker will find an excellent review of the field and a practical guide in this treatise. Although, as would be expected, specialists can find many omissions and certain interpretations with which they would disagree, in the main the various diseases are adequately considered from the standpoint of geographic distribution, etiology, pathology, symptomatology, treatment and prophylaxis. The authors have collected an immense amount of detail and have shown a nice discrimination in the comparative emphasis placed on the various subjects. The work is well illustrated, but it is to be regretted that so complete a work should contain so few detailed references to the literature.

Spontaneous Combustion. A Literary Curiosity. By John Rathbone Oliver. Boards Price \$2.50 Pp 27 with one illustration Chicago Argus Book Shop Inc 1937

Dr. Oliver was moved to write this pamphlet by the use which Dickens made of spontaneous combustion to remove a character in "Bleak House." Dr. Oliver has found similar records of spontaneous combustion in other early works of the nineteenth century. Apparently at that time the possibility of spontaneous combustion was accepted. He concludes that it was probably due to the fact that people drank much more pure spirits in those early days and that they came more frequently into contact with flames. Obviously a body thoroughly soaked with alcohol would burn much better than one which had not had the advantage of such inflammable material. The book is labeled "A Literary Curiosity. It is!"

Doctors on Horseback. Pioneers of American Medicine. By James Thomas Flexner. Cloth Price \$2.00 Pp 96 with 10 illustrations New York Viking Press 1937

The names of John Morgan, Benjamin F. Felt, Daniel Drake, William Beaumont, Crawford W. Long, and others who are the men whose biographies are the subject of "Doctors on Horseback" among the pioneer author tells their stories with a method that maintains interest well from the available material. Much material that previous biographies have analyzed of the characters of these

men who are more widely known. The author does not exaggerate these men but gives a true picture of them as they were in their practice and in their research. The book is nicely printed and is illustrated with some excellent portraits. Selected bibliographies and a good index complete the work.

A Brief Rule to Guide the Common People of New England How to Order Themselves and Thelrs in the Small Pocks or Measels. By Thomas Thacher. [First published in 1677/8 reprinted in 1800 and 1840.] Facsimile reproductions of the three known editions with an introductory note by Henry R. Viets M.D. Publications of the Institute of the History of Medicine the Johns Hopkins University. Fourth Series. Bibliotheca Medica Americana Volume I. Boards Price \$1.50 Pp 10 with illustrations Baltimore Johns Hopkins Press 1937

A Discourse upon the Institution of Medical Schools in America. By John Morgan. With an Introduction by Abraham Flexner. Reprinted from the first edition Philadelphia 1765. Publications of the Institute of the History of Medicine the Johns Hopkins University. Fourth Series. Bibliotheca Medica Americana Volume II. Boards Price \$1.00 Pp 41 with one illustration Baltimore Johns Hopkins Press 1937

These volumes come as publications of the Institute of the History of Medicine of Johns Hopkins University. They include in each instance a biographic note followed by a facsimile of the document mentioned in the title. They are certainly welcome editions to any medical-historical library.

Adaptation in Pathological Processes. By William H. Welch M.D. LL.D. With an Introduction by Dr. Simon Flexner. Reprinted from Transactions of the Congress of American Physicians and Surgeons 1897. Vol. IV pp 284-310. Publications of the Institute of the History of Medicine the Johns Hopkins University. Fourth Series. Bibliotheca Medica Americana Volume III. Boards Price \$1.50 Pp 53 Baltimore Johns Hopkins Press London Oxford University Press 1937

The two previous volumes in this series are Thomas Thacher's *A Brief Rule to Guide Common People of New England How to Order Themselves and Thelrs in the Small Pocks, Or Measels, 1677*, and John Morgan's *Discourse upon the Institution of Medical Schools in America, 1765*. The present volume reprints the presidential address by William H. Welch before the Congress of Physicians and Surgeons in Washington in 1897. Many older physicians will be glad of the opportunity to read (or reread) this brilliant 40 year old essay. In the words of the introduction, the essay is commended "to the attention of present-day students of medicine, to whom it should not fail to bring the pleasure and enlightenment enjoyed by an earlier generation."

Lungentuberkulose in Verbindung mit anderen Erkrankungen—ihre Häufigkeit und Behandlung. Von Dr. Klaus Briesch. Oberarzt am Tuberkulosekrankenhaus der Provinz Brandenburg zu Treuenbrietzen. 11 Heft Praktische Tuberkulose Bücherei. Behefte des Deutschen Tuberkulose Blattes herausgegeben von Kurt Klare. Paper Price 3.60 marks Pp 68 Leipzig Georg Thieme 1937

In this booklet a short but clear and well arranged survey is given of the problems arising from the coincidence of diseases of nontuberculous origin with an active tuberculosis. The main complications and their therapeutic management are given from the standpoint of treatment of the tuberculosis as well as of the complication. The book will be of value to the general practitioner as a source of quick orientation about the many problems that may arise. It is not comprehensive enough for the specialist. A rich and well arranged bibliography is added which will aid those who desire more detailed information.

The Specificity of the Wassermann Test in Syphilis. By E. H. Ruediger M.D. From the Department of Clinical Pathology, St. Joseph Hospital San Diego California. Paper Pp 8. The Author 1934

This little pamphlet reports on the accuracy of the Wassermann test with glycerinated human serum. The tests were applied to the blood serums of 306 student nurses, 206 pregnant women, 104 patients with malignant disease, 103 tuberculous patients and 106 with jaundice, and to the spinal fluids of 101 surgical patients. According to the author, the results demonstrated a high degree of sensitivity and accuracy, although no controlled comparisons with other methods were cited.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Trauma in Relation to Hernia, Hyperthyroidism and Neurocirculatory Asthenia—Napier, the plaintiff in this suit against the defendant railroad company, claimed that while he was riding as a passenger on the defendant's train the derailment of two cars caused him to be thrown against the seats and that as a result he had sustained a left inguinal hernia, which was followed by neurocirculatory asthenia and hyperthyroidism. From a judgment in the amount of \$7,500 for the plaintiff, the railroad company appealed to the Court of Appeals of Kentucky. The plaintiff's attending physician testified in his behalf as follows:

My diagnosis at first was a recurring hernia—may I say of traumatic origin? I took the patient's history in part as to that.

The next thing that ensued following this continuing my diagnosis was neuro-circulatory asthenia otherwise known as effort syndrome meaning concurrence known also as Soldier's Heart and caused by a greater than normal amount of adrenalin chloride in the blood stream the adrenalin coming from the adrenal or suprarenal [suprarenal] glands just above the kidneys and the adrenal glands arising from the same embryonic cell from which the sympathetic nervous system arises the sympathetic nervous system being that part of the nervous system which is composed of the ganglia or nerve stations along in front of the spinal cord in that portion running from the first dorsal vertebra to the last lumbar vertebra. This sympathetic nervous system goes to all the abdominal and all thoracic viscera and as stated arises from the same cell in uterine life or before birth or in the formation of a child that the adrenal glands arise from. For this reason they are closely related to the adrenal glands that are called the power house of the system. And in the presence of neuro circulatory asthenia they are always putting out more power than the sympathetic nervous system can use.

Then the next was hyperthyroidism which resulted from a hyper sensitivity of the thyroid gland to a presence of an over plus of adrenalin in the blood stream. This results in an overactivity of all the musculature in the entire body including the stomach and the intestines that is supplied with sympathetic nerves. Also the autonomic nervous system is undoubtedly affected and speeded up and we have what is known as hyperthyroidism or hyperkinesis which is an over action of the adrenal glands the sympathetic nervous system the thyroid and the anterior lobe of the brain.

The Court of Appeals interpreted this testimony to mean that the witness believed an excess of adrenalin chloride in the plaintiff's blood stream was apparently the moving factor in producing both the neurocirculatory asthenia and the hyperthyroidism. The witness also testified that the only causes of neurocirculatory asthenia are pain, hemorrhage, fear and worry, inhalation of anesthetics, infection, breaking down of the proteins, and asphyxia. He further testified that both the neurocirculatory asthenia and the hyperthyroidism from which the plaintiff suffered had been caused by a "breaking down of the proteins" which he described as a tearing of the muscles or a result of the tearing of the muscles, "the proteins" being "the amino acid of which the muscle is composed." He admitted that, although he had made many examinations for thyroid trouble, he had never before had a case of hyperthyroidism caused by a hernia. Another medical witness for the plaintiff also testified that the plaintiff was suffering from hyperthyroidism and neurocirculatory asthenia and that these conditions had been caused by the injury.

The plaintiff testified that he had had a hernia ever since he could remember but that it had been apparently cured by a herniotomy performed six years prior to the accident. Medical testimony indicated that a congenital hernia sometimes recurs even without apparent strain or injury. Physicians testifying for the railroad company stated that the plaintiff did not have hyperthyroidism either at the time of the accident or at the time of the trial. Several witnesses testified that there was no relationship between the hernia or the accident and hyperthyroidism. As to the alleged neurocirculatory asthenia one medical witness testified that if the plaintiff had not had a neurocirculatory asthenia at least to a relative extent prior to the accident he would not have had the original weakness of his abdominal musculature. Another witness stated that he was unable to name the causes of neurocirculatory asthenia but testified that a trauma severe enough to crush the body, break the bones and seriously destroy the soft tissue might produce a condition which would lead to it. Another witness testified

that there was no connection between a hernia and neurocirculatory asthenia and that an injury sufficient to produce a traumatic hernia would have caused a severe shock, accelerated heartbeat and chills, none of which signs and symptoms the plaintiff had ever manifested.

Apparently, the Court of Appeals did not believe that the plaintiff had sustained a traumatic hernia. It was pointed out that the plaintiff's own medical witnesses agreed that a traumatic hernia is accompanied by excruciating pain but the plaintiff's own testimony showed that he had suffered no such pain. Furthermore, his attending physician testified that he had first treated him for a congenital hernia rather than a traumatic one. The court further pointed out that this same witness admitted that an infection may cause the very condition which he ascribed to "the breaking down of the proteins," and the evidence showed that the plaintiff had suffered from infected teeth. Furthermore, there was evidence that the neurocirculatory asthenia existed prior to the accident. In the opinion of the court, the testimony with respect to the complications attributed to the accident was so highly speculative and vague as to be without probative value. Assuming that the evidence was sufficient to justify the submission of the case to the jury, the verdict of \$7,500 was in the opinion of the court flagrantly excessive and could not be allowed to stand. The judgment of the lower court, therefore, in favor of the plaintiff was reversed.—*Louisville & N R Co v Napier (Ky), 102 S W (2d) 1*

Dentists Retention of Dental Plate as Constituting Fraudulent Conversion—The defendant, a dentist, made a dental plate for a patient, the prosecutrix, and delivered it to her on her promise to pay him the amount charged for his professional services. Three months later the prosecutrix returned the plate to the dentist for an adjustment. At that time he demanded that she pay her bill and when she refused to do so he retained the plate on the theory that he was entitled to a lien on it for his services. He was later prosecuted and convicted under an indictment that charged him with fraudulent conversion. The dentist then appealed to the superior court of Pennsylvania.

The facts, said the superior court, do not warrant a conviction under the fraudulent conversion act. Under that act, any person having possession of any property belonging to any other person and who fraudulently withholds, converts or applies it to and for his own use and benefit is guilty of a misdemeanor. The statement of the lower court that "the defendant supposed he had a right to hold the plate" of itself negated the idea of a fraudulent conversion. The act requires an intent fraudulently to withhold, convert or apply the property of another. There was no evidence of such an intent. If there was a disputed question of title to the plate, the prosecutrix could have enforced her rights in an action of replevin or in a civil action for the value of the plate. The superior court reversed the judgment of conviction and discharged the dentist.—*Commonwealth v Irene (Pa), 190 A 171*

Evidence Admissibility of Examining Physician's Opinion Based on Subjective and Objective Symptoms

—The plaintiff, Brouette, sued the defendant utilities company to recover damages for injuries sustained as a result of an explosion in a building supplied with gas by the defendant company. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Wyoming.

At the trial, three expert medical witnesses who had examined the plaintiff for the purpose of testifying later at the trial were permitted to give their opinions as to the extent and permanence of the plaintiff's injuries, based in part on statements made by the plaintiff to the physicians during the examinations. The Supreme Court agreed with the defendant that this testimony was inadmissible. As is stated in 22 C J 269, 270, a physician who examines a plaintiff not for purposes of treatment but for the purpose of qualifying as an expert witness relative to the extent and permanence of the plaintiff's injuries should when testifying, base his opinion on objective symptoms discovered by his examination or on assumed facts contained in a proper hypothetical question or on a combination of the two and not on what was told to him by the injured person. When it becomes necessary and is competent for an expert witness to base an opinion partly on statements made to him by

a plaintiff, the substance of such statements should be disclosed so that the jury may judge whether they conform to the actual facts as shown by the evidence. Under such circumstances the jury should be cautioned by the court to disregard any opinion based in part on assumptions of nonexistent facts. While the court was of the opinion that the questioned testimony was improper and should not have been admitted, it did not believe that its admission constituted reversible error. The testimony was largely cumulative and of a nature similar to that given by another medical witness to which the defendant had taken no exception.

Accordingly, the Supreme Court affirmed the judgment in favor of the plaintiff—*Northwest States Utilities Co v Broulette (Wyo)*, 65 P (2d) 223

Dental Practice Act Effect of Repeal and Reenactment of Dental Practice Act, with Amendments, "Moral Turpitude" Construed—The defendant was licensed to practice dentistry in Maryland in 1926. In December 1935 the Dental Examining Board revoked his license on the ground of conviction of a crime involving moral turpitude. The defendant instituted mandamus proceedings against the board in the Baltimore city court, that court canceled the revocation order, and the board appealed to the Court of Appeals of Maryland.

The dental practice act under which the defendant was licensed was passed in 1920. In 1933 the legislature repealed the earlier act and reenacted it, with amendments. Section 11 of the 1933 act provided:

Nothing in this Article, or in any other provision of this Code, shall be so construed as to interfere with the rights and privileges of persons holding certificates duly issued to them by the State Board of Dental Examiners of Maryland prior to the passage of this Act.

The effect of this provision, the defendant contended, was to deny to the board of dental examiners the right to revoke his license since he was licensed under the act existing prior to the 1933 act. With this contention, however, the Court of Appeals disagreed. The section quoted, said the court, was a repetition and reenactment of a similar section contained in the act of 1920, which was in effect when the defendant was licensed to practice dentistry and which was not even interrupted by the act of 1933 and was as much in force as if it were still the act of 1920. The law in Maryland with respect to the repeal and reenactment of statutes, said the court, was clearly set forth in the case of *Ireland v Shipley* 165 Md 90 166 A 593, as follows:

It is also settled law in this state that where a statute is repealed and reenacted with amendments and the amended statute contains substantially the same provisions as the original the continuity of the original as to those provisions is not affected.

The court held, therefore, that the state board of dental examiners was not lacking in authority to hear and determine the charges preferred against the defendant.

In the revocation proceedings, the board charged that the defendant, on three separate occasions had been arrested on charges of indecent exposure, and that he pleaded guilty in each instance and was convicted. The defendant contended, however, that a conviction of the offense of indecent exposure did not constitute a conviction of an offense involving moral turpitude. Lexicographers and courts agree said the Court of Appeals, on the definition of 'moral turpitude' but courts do not agree on its application. Bouvier's Law Dictionary (Rawle's Third Rev.) 2247 defines it as 'An act of baseness, vileness or depravity in the private and social duties which a man owes to his fellow men or to society in general contrary to the accepted and customary rule of right and duty between man and man'. The word 'turpitude' is defined in the Oxford Dictionary as "Base or shameful character; heinous vileness; depravity, wickedness". The word moral in combination with the word "turpitude" is the court said a figurative expression which does nothing more than attach a moral character to the word "turpitude". The court knew of no authority which held that a charge of indecent exposure constituted an offense involving moral turpitude, but the court thought it required no such authority to prove that the offense is such as to reflect on the character of the offender and that the offender not wanting in decency and morality. The defendant admitted that he had been convicted of the offense of "indecent exposure" three times.

mony before the said Board showed that he had not committed the offense in any public place and that the circumstances were entirely accidental." But, the court said in answer of the board to which the defendant demurred stated facts showing that the exposures were public and intentional. It has been held that an act does not involve moral turpitude unless it was intentionally done or was not innocent in its purpose. In the opinion of the court, however, this was neither the time nor the place for the defendant to protest his innocence or to contend that the offenses were accidental or unintentional. His protestations were not consistent with his previous pleas of guilty to a charge which, if unfounded, should have been resisted. The pleas and convictions implied publicity and intention. The first plea and conviction, occurring in 1931, might have been overlooked or dismissed as too remote the court said, but it cannot now be overlooked when considered with two similar offenses committed within four days in February 1935. The defendant thus practically forced the board of dental examiners to act. The court, therefore, reversed the order of the Baltimore city court canceling the revocation of the defendant's license—*Brun v Lazzell (Md)*, 191 A 290.

Chiropractic Revocation of License Not Barred by Statute of Limitations—On March 8, 1930, a complaint was filed with the California board of chiropractic examiners charging that Hartman, a licensed chiropractor, had employed fraud and deception in applying for his license in that he falsely stated in his application that he had never been convicted of a crime involving moral turpitude. The complaint charged that Hartman, on Nov 2, 1916, had been convicted of murder in the first degree. So far as the record shows, no action was taken on this complaint until Aug 2, 1936, when a hearing was had at which Hartman was present and testified. A certified copy of the judgment of conviction of murder in the first degree was introduced in evidence, showing that Hartman was sentenced to the state prison for life. It was further shown, however, that the life term was subsequently commuted and that Hartman served the commuted term. The board revoked Hartman's license, the superior court, city and county of San Francisco upheld the revocation, and Hartman appealed to the district court of appeal, first district, division 1, California.

Hartman contended, among other things, that the crime for which he was convicted was not a crime involving moral turpitude. The court, however, dismissed this contention as without merit and further observed that the commutation of the sentence did not nullify the original sentence or lessen the offense but merely substituted a lesser for a greater punishment. Hartman further contended that the proceeding to revoke his license was barred by the statute of limitations, but, said the court, the statute does not apply to revocation proceedings. *Bold v Board of Medical Examiners (Calif)*, 133 Cal App 23, 23 P (2d) 826.

In a recent case, said the court it was held that prohibition will not lie to restrain the revocation of licenses by boards of this character, the function of the board in such proceedings being administrative and not judicial. *Whitten v California State Bar (Calif)*, 65 P (2d) 1296. For the same reason certiorari will not lie. There being no facts in the present case that in the opinion of the court warranted other relief, the judgment of the superior court upholding the action of the board of chiropractic examiners in revoking Hartman's license was affirmed—*Hartman v Board of Chiropractic Examiners (Calif)*, 66 P (2d) 705.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Criteria for Diagnosis and Cure of Rheumatoid Arthritis—Cecil considers the criteria necessary for the diagnosis of rheumatoid arthritis by dividing them into pathologic clinical, roentgenologic and serologic observations. A patient with rheumatoid arthritis should present the picture of a chronic progressive multiple arthritis characterized in its earlier phases by swelling of the soft tissues and in its later stages by some ankylosis and deformity. Implication of the interphalangeal, metacarpophalangeal and wrist joints is especially characteristic. The synovial membrane and the subcutaneous nodules, when present, show specific histologic changes. The roentgenographic evidence is quite typical, and the patient's serum in a large majority of cases will induce an agglutination of the hemolytic streptococcus. A rapid sedimentation rate of the red blood cells is highly characteristic but is seen in other forms of infectious arthritis as well. The first criterion for determining the cure of rheumatoid arthritis should be clinical cure evidenced by freedom from pain and swelling of the joints and partial or complete return of function of the joint. In addition the patient should feel well and should be entirely relieved of the exhaustion and fatigability which so frequently accompany the disease. In a cured case the sedimentation rate of the red cells should return to normal and the specific agglutinins for the hemolytic streptococcus should disappear from the patient's serum. The leukocyte count returns to normal and the secondary anemia is replaced by a normal blood count. The patient should not be considered as cured until he has remained free from symptoms for at least one to two years. The author thinks that if the curative effects of the numerous types of

therapy were analyzed with such criteria in mind, perhaps fewer but more intelligible contributions on the treatment of rheumatism would be made.

Lymphosarcoma Cell Leukemia—Of the forty-three patients with known lymphosarcoma that Isaacs has encountered, a leukocytosis developed in fifteen (ten men and five women) during the course of the disease. There were eight positive biopsies and six necropsies. The ages of the patients ranged from 6 to 70 years. To observe how a lymphosarcoma cell would appear if it was in the blood stream, pieces of fresh lymphosarcoma glands were stirred in blood serum, and films were made of this suspension. These were stained with Wright's stain alone or preceded by brilliant cresyl blue while the cells were in the moist state. The cells are not lymphocytes but lymphosarcoma cells, so that the condition is a true lymphosarcoma cell leukemia.

Surgical Management of Ptosis—Jameson describes an operative technic for the management of ptosis in which the following principles are involved: 1 Use is made of the entire strength of the unutilized superior rectus muscle. 2 A direct incision is made into the cartilage, with entrance into a pocket prepared for the reception of the folded muscle, instead of the incision into the levator muscle or the tarso orbital fascia into the postorbital region. 3 The muscle is shortened and consequently the lid is elevated by the folding of the attached muscle on itself prior to its introduction into the pocket and the tarsus is elevated by placing the incision in the cartilage farther below the curve. 4 The folded shortened muscle is attached securely. The author believes the new operation is a stronger, simpler, quicker and less complicated procedure than the Motais operation and one which by reason of its flexibility of gradation and shortening is attended with a higher return of correction. He has performed the operation in eight cases with success.

Formation of Preretinal Connective Tissue in Vitreous—Knapp states that the opacities of the vitreous which accompany acute exudative choroiditis usually become absorbed in time and do not interfere with vision unless the choroidal focus invades the macular region. Sometimes a band of opacity remains which extends from the nerve head to the area of choroidal atrophy. A more unusual permanent change is the opacity of the vitreous observed in three cases. The vitreous is clear except for this opacity, which is situated just in front of the retina and seems to have a predilection for the macular region. The opacity adheres to the retina and is irregularly branching, whitish of varying thickness in the center and fading out at the periphery. It seems anchored to the internal membrane of the retina. It always covers the retinal blood vessels and newly formed capillaries do not penetrate the opacity. In this respect it differs from retinitis proliferans. Nor does it ever detach the retina or even exert any traction. The opacity tends to become thinner, though it never disappears and final vision is often surprisingly good. The choroidal lesion is always large and not connected with opacity of the vitreous.

be drawn between the initial lesion, the duration of treatment and the cystometric observations. In the cases in which cystometry was employed the bladders dealt with were compensated, as was evidenced by the absence of residual urine, freedom from urinary symptoms and infections. Four patients had normal cystometrograms, four, while apparently within normal limits, had a latent desire to void and gave at least suggestive signs of an early neurogenic involvement, and sixteen patients had prediagnosed neurogenic bladders based on the usual criteria for interpretation. Cystoscopy was performed in seventeen cases. Four cases showed neurogenic bladders cystoscopically. In five cases the observations, while suggestive, alone were insufficient for a definite diagnosis. In three cases cystoscopy was apparently negative, while the cystometrograms demonstrated neurogenic bladders.

Operative Treatment of Urinary Stone—Quimby declares that a proper medical decision should be made as regards treatment in every instance of renal calculus, at the first onset of symptoms. Such a decision is aided by a minute study of the history, symptoms and physical examination. Each instance of urinary stone must be studied in detail before a proper decision can be taken as to the best course to pursue—whether

nonoperative or operative. If operation is to be undertaken, every effort must be made to rid the kidney entirely of all calculi. Much help in this regard is furnished by the portable x-ray apparatus, the suction tube and the coagulating electric current. By their use the surgeon is enabled to save many kidneys in cases that would otherwise terminate in undesirable nephrectomies.

Cutaneous Eruptions in Gonorrhea—Levin and Silvers discuss the cutaneous complications of gonorrhea and classify them into two principal groups: (1) the localized forms that occur usually in the neighborhood of the primary focus of infection and result from direct infection of the skin by the gonococci or as a result of irritation by the secretions and secondary infections by alien bacteria and (2) the generalized forms, probably metastatic, and caused by the transport of the gonococci by the blood stream to the skin, at which point eruptions result from the action of the micro-organisms and their toxins. It is difficult to correlate the macular, papular and urticarial eruptions positively with the gonococci in suspected cases. The specificity of the keratodermic type of the blennorrhagic eruption has frequently been questioned by some because of the similarity of this eruption to certain clinical forms of psoriasis. The definite clinical course of keratoderma blennorrhagica in one of the authors' patients ruled out any suggestion of psoriasis. There was no personal or familial history of psoriasis before the onset of the illness. The patient had a gonococcal urethritis, which was followed by involvement of the joints and cutaneous complications. The heaped-up character of the lesions, which suggested crusts rather than the scales of psoriasis, and the acute nature of the illness, all pointed to gonococcal infection. A positive blood culture was not obtained nor were the organisms recovered from the lesions. The hemorrhagic form of cutaneous eruptions suggests gonococcal septicemia in which the important clinical data to be taken into consideration are the history of a local gonococcal infection, the spiking temperature curve, the progressive anemia, the leukocyte count, the gonococcus complement fixation test, a positive blood culture and the localized areas of purpura indicating embolic phenomena. A positive blood culture may be obtained at times. One case showed unmistakable evidence of gonococcal septicemia at post-mortem examination, yet repeated blood cultures had been sterile. Unless these lesions are kept in mind by the clinician in suspected cases of gonococcal septicemia they may easily be overlooked. At times less than half a dozen may be present, and in rare instances because of the lack of a bright red color and the presence of a brownish tinge they may be confused with lentigo.

Sulfanilamide—Millett reports a case of type 3 pneumonia involving one lobe twenty-four hours after onset. The patient was given 1 Gm of sulfanilamide on the third day. The next morning there were signs of frank consolidation in the left upper lobe with bronchial breathing and whispered pectoriloquy. Thirty-one hours after the institution of sulfanilamide therapy the temperature had dropped from 104.2 to 99.4 F. For the next two days the temperature averaged 100 F and then dropped to normal. Sulfanilamide was continued until another 15 Gm had been given, a total of 25 Gm in about three and one-half days. The only untoward effect noted was a moderate cyanosis of the lips, which persisted until discharge, on the morning of the tenth day.

Practical Methods of Reducing Cancer Death Rate

Since cancer is a preventable disease Skinner believes that the recognition, knowledge and utilization of the following factors in its diagnosis and treatment will reduce the mortality rate of cancer: the beginning of cancer from a single spot perhaps unicellular, in tissue or organ, chronic or persistent irritation as the most useful and practical causal element in cancer; the early diagnosis and prompt eradication of the lesion by surgery or radiation therapy, biopsy study by pathologists and basing its treatment on tumor grading and sensitivity to radiation. Total surgical excision of cancerous growths is jealously maintained and with a more courageous completeness but the partial extirpation of any cancer is condemned. Surgical cure for intimate radium therapy is a valuable venture. The use of well executed radium therapy for the superficial nodules and metastases to the skin, mouth lip and cervix is universal, but there must be insistence on the use of lethal and homogeneous radiation therapy for comfort and low expense of radium therapy. Radium is increasingly available throughout the world. It occupies a distinct field, especially in malignant states. It may afford relief from pain, delay death, and it continues as a research of increasing merit. Educational propaganda

between that which is professional and that which is popular. The professional appreciation of cancer facts and fancies is far more important than lay education because, if physicians are not practicing the early diagnosis of cancer, what good does it do to advise potential or inquiring patients to consult their physicians?

Relation of Heredity to Occurrence of Cancer—She maintains that, in order to breed out cancer, human records are imperative. The necessity for human records is the same, irrespective of any details of a genetic theory, indeed, they would in time prove the correctness or the error of any genetic theory, and they would be the court of last appeal. Any step actually to breed out cancer may lie far ahead, but the glory will be to those who actually do it, and when it is done it will be a routine procedure. If specific types and sites of tumor can be ruled out of mouse families, they can be ruled out of human families. This future procedure can be made possible by the simple method of taking adequate records now and assembling them in a central bureau where they can be of service. A study of such human records would show the attending specialist the probable type of diseases to be expected in a family as the result of ancestry, the meaning of symptoms, sometimes fatally hard to ascribe to their cause but which have been presented before in the family, the probable reaction to types of treatment, and the probable prognosis. These things the author can predict in her mice from knowledge of the family records. This pre-knowledge of probable diseases, reactions and prognosis within a family would, she thinks, if it were universally at the command of practitioners, revolutionize medicine, since one should then know something not only about the disease and its treatment of choice but also about the patient.

Comparison of Gastroscopic and Roentgen Observations—Schindler and Templeton declare that gastroscopic and roentgenologic studies should be considered as cooperative rather than competitive examinations. Either method may visualize lesions that the other cannot. Shape, contour, motor function and gross lesions are better seen roentgenologically, while mucosal changes and smaller lesions are better seen gastroscopically. In most cases the roentgenogram of the gastric mucosa bears little resemblance to the patterns seen by the gastroscopist, and sometimes changes clearly discernible at repeated gastroscopic examinations may be entirely undetectable by the roentgenologist. Conversely, the roentgenologist sometimes sees changes that are invisible to the gastroscopist. The frequent failure of the gastroscopist to see radiating folds of the sort so often seen roentgenologically in cases of gastric ulcer suggests that these folds are not true rugae but, instead, wrinklins caused by changes in the submucosa or the muscularis. This may explain why roentgenologists sometimes see thickened folds in atrophic gastritis, a condition often marked by thickening of the submucosa beneath the atrophic mucosa. Obviously, gastroscopy is best suited to the study of the mucosa, roentgenology to the study of the deeper gastric tissues.

The Black Widow Spider in Minnesota—Denning points out that the black widow spider has been found in southeastern Minnesota. Three female specimens were taken, at points a few miles from one another. All were found on the sun-baked sides of hills, where they had built an irregular web about a protruding stone. A method by which the black widow may become further distributed is shown in the finding of male *Latrodectus mactans* at Hallock, Minn., the spider having been carried from Mississippi in a truck load of bales.

Plasma Lipoids in Lipemia—With the thought that a study of the proportions of the various lipoids in the plasma would indicate the stage at which accumulation occurred, Herbert performed such analyses in eight normal subjects, seven cases of renal edema, one case of lipemia in the terminal stage of chronic nephritis, one case of nondiabetic xanthoma and one case of gross diabetic lipemia with xanthoma. The normal values for the various lipoids fall within the accepted normal ranges, except in the case of glyceride, for which low values were obtained. The iodine values of the separated fatty acids normally range from 79 to 124, with an average of 105. In lipemia associated with renal edema, all the lipid fractions are increased, the glyceride forms a larger proportion of the total than normally, the free cholesterol and cholesterol ester form about the normal proportion of the total lipoids, and the phospholipin is relatively decreased. In one case in which kidney lipoids were analyzed there were extensive deposits of cholesterol ester in the kidneys in the absence of any significant increase in plasma lipoids. The case of nondiabetic xanthoma showed a type of lipemia similar to that found in renal edema. In gross diabetic lipemia, when the glycerides form a very large proportion of the total lipoids, the iodine values of the separated fatty acids tend to be low. In general it seems that many pathologic lipemias of moderate degree show similar changes. The lipoids in circulation probably represent a mixture of those mobilized from reserve stores and those mobilized from the liver.

Menstrual Periodicity—The Gunns and Jenkin collected menstrual data from normal women by a postal method in which tests of reliability were possible. The 770 women providing periodicity data were divided into (1) 209 reliable (2)

270 fairly reliable and (3) 291 unreliable subjects. They find that 90 per cent had an average interval between the onsets of successive menstruations lying between twenty-five and thirty-six days inclusive, 3 per cent had an average of thirty-seven days or more and 7 per cent an average of less than twenty-five days. Only about 2 per cent had an average of less than twenty-four days. The average interval did not show any predilection for whole weeks. The average for all cases in sections 1 and 2 was twenty-nine \pm 0.19 days, the commonest averages lay between twenty-six and twenty-nine days. No instances were found that did not vary by at least 275 days between the shortest interval and the longest. The duration of one interval is not influenced by the duration of its predecessor. Among the professional classes which composed the series, a correlation between occupation and average interval was absent. Marriage did not appear to affect the periodicity. There was a progressive decrease in the average interval with increasing age amounting to one day in five or six years. There was no tendency for the interval to vary with the seasons of the year. There appeared to be a slight tendency for menstruation to start in the latter part of the working week. No connection could be detected between menstruation and the moon in the data of more than 10,000 menstruations.

Effect of Vitamin C on Coagulability of Rabbit Blood—To determine the origin of the hemostatic mechanism of vitamin C, Terazawa and his associates studied its effect on the coagulation of rabbit blood. Vitamin C accelerated the coagulation time of rabbit blood and the change in blood elements that is, the increase of blood platelets, fibrinogen and thrombin probably participated in this hemostatic mechanism of the vitamin. Originally this hemostatic mechanism is initiated by a change in the nature of the blood or owing to the accelerated coagulation time by a stimulation of the hemopoietic organs or by the effect on the vascular walls themselves. Vitamin C had action on the former two.

*Decaffeinated Coffee and Denicotinized Tobacco in Gastric Diet P
Bernay and G Faure—p 865

Decaffeinated Coffee and Denicotinized Tobacco in Gastric Diet—Bernay and Faure point out that in patients with gastric ulcer, hyperchlorhydria, hypersecretion, gastralgia and even hypochlorhydria, it is often necessary to forbid coffee and tobacco on account of their stimulating action on the gastric secretion. Patients who have been told to abstain from coffee and tobacco ask whether they are permitted to substitute decaffeinated coffee and denicotinized tobacco. To decide this question the authors made tests on the gastric secretion and reached the conclusion that tobacco is a powerful stimulant of the gastric secretion. The figures obtained in the tests with tobacco are comparable and even superior to the figures obtained with the test meal. Denicotinized tobacco produces practically the same results. Tests with denicotinized tobacco revealed rather high values of hydrochloric acid and large volumes of gastric juice, but its action seemed less regular than that of ordinary tobacco. Decaffeination, no matter to what extent, does not suffice to suppress the stimulating action of coffee on the gastric secretion. The figures obtained with decaffeinated coffee are generally comparable to those produced by ordinary coffee or by the test meal. To forbid the use of coffee, even of decaffeinated coffee, is thus well founded and to forbid the use of tobacco, denicotinized or not, is no less justified in patients with gastric ulcers and with hypersecretion. It is necessary to forbid the use of tobacco to all dyspeptic persons, when fasting or between meals, because it leads to an acid secretion that exhausts at the wrong time the secretory potentialities of the stomach. However, for patients with hyposecretion, coffee and tobacco remain permissible only after a meal.

Male Hormone Therapeutic Indications and Results L de Gennes
and R Roge—p 821Variations of the Histophysiology of Female Genitalia R Courrier
—p 829*Contribution to Study of Blindness of Hypophyseal Origin. Four Cases
of Adiposogenital Syndrome with Retinal Degeneration and Mental
Backwardness P Pesme and G Hirtz—p 833Hypophysis, Thyroid Parathyroid Genital Glands Adrenals Hormones
and Hormone Regulations J Sigwald—p 839

Blindness of Hypophyseal Origin—Pesme and Hirtz recently observed four cases of a curious hereditary and familial syndrome that is characterized by adiposogenital dystrophy with mental backwardness and retinal degeneration. The authors describe these cases not only because of their rarity but also because they show the role of the hypophysis in the development of the syndrome and particularly the ocular lesions. The authors direct attention to the similarity of the disorder to the Lawrence-Biedl syndrome. The described cases differ from those designated as the Lawrence-Biedl syndrome by the absence of malformations of the members (syndactylism or polydactylism). There seem to be three symptoms that characterize the typical as well as the atypical cases: obesity of the hypophyseal type, mental backwardness and retinal disorders. The retinal symptoms are especially noteworthy in all cases: there was a degeneration of the retina with discoloration and hemeralopia. One of the patients was given extracts of the entire hypophysis for a year, but this form of treatment failed to produce the slightest improvement. After a new examination it was decided to treat the patient with extract of the anterior lobe of the hypophysis and with several other glandular extracts (thymus, thyroid, adrenals and total hypophysis). Under the influence of this treatment the patient lost weight and increased in height, moreover, the genitalia developed normally and the hands and fingers, which had been contracted and deformed, assumed a normal shape and the nails lost their imbricated appearance. All aspects likewise changed in that the patient became active and bright. Even more remarkable was the improvement of the ocular defects. The boy was able to read and to write.

being disturbed by nystagmus and the photophobia disappeared. Measurement of the visual acuity revealed hardly any increase but the boy was better able to utilize his visual powers. On the basis of this observation, the authors conclude that the hypophysis influences not only the fat metabolism and the development of the genital organs but also the retina. Such a relationship between the retina and the hypophysis had already been suggested by other investigators and the authors think that treatment with hypophyseal hormones may perhaps prove valuable in some congenital retinal defects.

Rapid and Economic Method of Delousing—To destroy body lice Lebaillly places the infested person, dressed in a shirt and the trousers loosened at the waist, into a specially constructed cabinet. All the clothing and the personal belongings of the person are likewise placed in the cabinet. Even the head is enclosed in a covering that is attached to the cabinet, but the eyes, nose and mouth are left free. After the cabinet has been closed and the head covering properly adjusted, sulfur is ignited in the cabinet. The sulfur anhydride vapors that develop penetrate everything in the cabinet. After all the oxygen in the cabinet has been consumed by the combustion, the sulfur is extinguished but the cabinet is left closed for twenty minutes. At the end of this period all parasites are dead and the person can be taken out of the cabinet, but in order to prevent the escape of a cloud of suffocating gas it is first suctioned off, which requires about four minutes. The garments are shaken in the air and then the patient can dress himself again. The entire procedure requires about thirty-five minutes and the expense is about 1 franc (4 cents). It is absolutely necessary to repeat the procedure eight days later, for the eggs that were laid just before the sulfur treatment are hatched six days later and the new lice must be destroyed. This method of delousing does not damage the garments, and the persons treated in this manner made no complaints. The author recommends the method for use in hospitals, night shelters and welfare stations, particularly if there is danger that diseases such as recurrent fever or exanthematous typhus might be propagated by the lice. In persons who have only head lice, the use of the cabinet is unnecessary. The author constructed a special helmet, which leaves the eyes, nose and mouth free but closes tightly about the face and neck. This helmet is inflated with sulfur anhydride vapors through a tube that is connected with a generator of the gas. The helmet is left on for twenty minutes. After eight days the treatment is repeated. The author suggests that the treatment be given outdoors, perhaps in the school yard. He considers this method of destruction of head lice especially valuable for schools and summer camps.

Action of Thyroid Hormone on Immunity—Rocchini gave guinea pigs subcutaneous injections of antityphoid vaccine either alone or combined with extract of total thyroid. He found that the thyroid extract simultaneously administered with the vaccine stimulates the production of specific antibodies (agglutinins). The agglutinating power is higher in the blood serum of animals which are given the thyroid extract than in

the controls, but the former are less resistant than the latter to the development of infection induced by the inoculation of living and virulent typhoid bacilli. The thyroid treatment does not stimulate the skin sensitivity to intradermal reactions to killed typhoid bacilli.

Blocking the Reticulo-Endothelial System—Cosentino blocked the reticulo-endothelial system of rabbits by intracardiac injections of 2 cc each of a 1 per cent solution of trypan blue in physiologic solution of sodium chloride. One injection was given every other day up to ten injections. The amount of calcium, phosphorus and magnesium in the serum of cardiac blood was determined before, during and after the induction of the block of the reticulo-endothelial system. The animals as well as the controls were kept in the same conditions of environment and diet before and in the course of the experiment. The stain did not seem to be highly toxic. The conjunctiva and then the skin turned blue. Hypercalcemia, hyperphosphatemia and hypomagnesemia appeared early in the experiment and increased as the block of the reticulo-endothelial system increased.

Roentgen Irradiations in Diabetes Insipidus—Cignolini's treatment consists of three series of roentgen irradiations, which are given on the anterior and posterior regions of the knee joints (with the legs placed together during the treatment), the right hip and shoulder joints and the left hip and shoulder joints. Each series consists of ten treatments, each of which is given daily on one of the different fields to be irradiated. The dose varies from 160 to 200 roentgens administered through a filter of 0.5 mm of zinc and 2 mm of aluminum. Larger doses may induce nausea. Drugs and hypophysis extracts are not administered in the course of the treatment. The ovaries, thoracic organs and head are protected against the irradiations. The best results of the treatment are obtained when it is given in association with short wave irradiations, either over the hypophysis or the ovaries or sometimes on the breast. The short wave treatment is given daily for twelve minutes until the number of applications has reached ten, thirteen and twenty during the first, second and third roentgen series, respectively. At the end of the first series of roentgen treatments, polyuria is greatly diminished. At the end of the entire treatment it is normal and it remains so after discontinuation of the treatment. Four or five months should elapse between the first and second treatments and one or two months between the second and the third (last) treatment. There are no late complications, such as cutaneous lesions and anemia. The author reports a case in which a woman suffered from a neurohypophyseal syndrome (obesity, amenorrhea and diabetes insipidus). Diabetes was grave and had not improved under different treatments. The associated roentgen and short wave treatment induced spontaneous reappearance of menstruation with a normal cycle and controlled polyuria. The satisfactory results of the treatment persist at the present time more than a year after discontinuation of the treatment.

Variations of Venous Blood Pressure—Audap-Soubie made determinations of the venous blood pressure in a group of patients who had normal cardiovascular and renal apparatus, with the exception of one who had heart disease. The determinations were made on patients with a fasting stomach after administration of 1,000 or 1,500 cc. of water. According to the author there is not a "standard" figure for the venous blood pressure, which is different in each case and changes at different times and on different days. It changes also after ingestion of water or liquid food and follows the curve of elimination of liquids. In the majority of cases the figures of the venous blood pressure are higher than those of the maximal arterial blood pressure. The figures in the former are given in millimeters of water, whereas those in the latter are given in millimeters of mercury. According to the author it is advisable to make the determinations of the venous blood pressure in patients with fasting stomachs for a more uniform evaluation of the results.

Chemical Processes in Normal and Pathologic Muscle S Grzycki and W Guca —p 1387

Tongue and Gastric Ulcer L von Friedrich —p 1390

Increase in Rest Nitrogen During Diabetic Coma—Gopfert says that among the complications which may develop in the course of diabetic coma there are several which have been ascribed to a disorder in the renal activity. He mentions several of these symptoms but points out that they almost never occur together and that the one or the other develops without noticeable regularity. He thinks that this factor makes it improbable that renal insufficiency is the only cause, for, if such is the case, a greater uniformity in the symptomatology would exist. He is inclined to assume that renal defects, circulatory disturbances and metabolic anomalies work together and that, depending on the predominance of the one or the other, different symptoms predominate. The eliciting factor of albuminuria, cylindruria and hematuria is an impairment of the uriferous tubules, which in turn is caused by the elimination of the large quantities of ketone bodies. As is proved by necroptic studies on patients who died in diabetic coma, the glomeruli do not undergo changes. Thus there is no justification for ascribing an increase in nitrogen rest, which is observed in many cases of diabetic coma, to an insufficiency in the excretory apparatus of the kidney. If, in case of normal renal function, fluctuations of the rest nitrogen occur during diabetic coma, fluctuations in the blood sugar usually exist simultaneously because rest nitrogen and dextrose originate in the same source, that is, in the transformation of protein into dextrose. In this case the increase in rest nitrogen is the result of a complete depletion of the glycogen depots of the organism. If, however, during the diabetic coma there develops an increase in the rest nitrogen without simultaneous increase in blood sugar, a complicating renal defect exists which has impaired the renal function.

Difference in Action of Vitamin D₂ and D₃—Brockmann says that numerous experiments have been made in order to solve the problem of identity of the antirachitic vitamin in cod liver oil with that of irradiated ergosterol. In rachitic rats

these two substances showed identical therapeutic effects, whereas in rachitic chickens they did not. Although it had been assumed that the active factors in cod liver oil and in irradiated ergosterol are different chemically, the definite proof for this had not been furnished until recently, when Windaus and his collaborators clarified the nature of vitamin D₂ and isolated vitamin D₃ from certain fish oils and identified it with the D₂ which is prepared from cholesterol. Since animal experiments had demonstrated the therapeutic superiority of vitamin D₂ over vitamin D₃, the author decided to try vitamin D₂ in rachitic infants. He reports his observations on twenty-one rachitic infants. The vitamin D₂ was given in doses amounting to about half of those given in medication with vitamin D. The therapeutic results demonstrated the superiority of vitamin D₂ over vitamin D₃.

Dioxyacetone and Hepatic Function During Pregnancy

—Dietel says that various functional tests have been recommended to determine disturbances in the hepatic function during pregnancy. In a former report he described comparative examinations with a number of the functional tests of the liver, which proved that the tests produce contradictory results. Of the tests for the carbohydrate metabolism, the galactose tolerance test proved to be the most reliable for clinical purposes. However, Wachstein and Eppinger believe that the tolerance test with dioxyacetone is an even more reliable hepatic test. The author decided to make the dioxyacetone tolerance test in women who were free from hepatic disturbances and who were not pregnant and in another group of women who were pregnant. He found that, following a tolerance test with 40 Gm of dioxyacetone, pregnant women often show a slightly higher dioxyacetone content of the blood than do women who are not pregnant. However, the pregnant women do not show pathologic values or, if such values do occur, a repetition of the test generally reveals a normal reaction. Thus in the majority of pregnant women the dioxyacetone test gives no indication of the existence of a hepatic impairment.

Hyperemesis Gravidarum—Ohligmacher reports observations on ketonuria in hyperemesis gravidarum. The development of the ketonuria indicates an inadequate supply of carbohydrates. The intake of sufficient amounts of carbohydrates is of great importance in pregnancy and particularly if hyperemesis develops. The daily examination of the urine of patients with hyperemesis gravidarum for the presence of ketone bodies makes it possible to supervise the adequate intake of carbohydrates. For this reason it is indispensable in the treatment of such patients.

Ninhydrin for Demonstration of Cancer in Serum

Weiss says that the ninhydrin reaction for cancer was introduced by Lehmann-Facijs and Witting in 1934. Serum is withdrawn from the fasting patient at a preparatory trial conditions, combined with normal serum from a healthy and incubated. Then the coarse molecular products are precipitated by boiling with 96 per cent alcohol. The cleavage products (for instance tumor products) are precipitated and can be demonstrated in the filtrate by the ninhydrin

(blue color reaction). Weiss employed this test in 447 cases, 178 patients with carcinoma, thirteen with sarcoma, fifteen with other tumors and 241 without malignant growths. He reaches the conclusion that the ninhydrin reaction according to Lehmann-Facijs is a relatively simple method for the demonstration of cancer. About the reliability of the test he says that in 178 cases of carcinoma it failed thirty times, that is, it produced correct results in 83.1 per cent of the cases. In the cases without carcinoma, the results were 86.4 per cent correct.

Electrocardiogram in Experimental Poisoning—For his experiments Weber used the toxins of diphtheria, *Bacillus botulinus* and tetanus. He injected subcutaneously or intravenously 1 cc doses of diphtheria toxin in dilutions of 1:50, 1:100, 1:200 and 1:1,000 in sixteen rabbits, intravenously 1 cc doses of *Bacillus botulinus* toxin in dilution of 1:200 in eight rabbits and 1 cc doses of tetanus toxin in dilution of 1:50 and 1:100 in a large number of rabbits. Each time the dilutions were freshly prepared. Electrocardiograms were taken every day. The experiments show that tetanus toxin has no toxic influence on the cardiac muscle. In experimental poisoning diphtheria toxin causes marked changes in the electrocardiogram showing damage to the system of conduction in all its segments, most often the signs of toxic damage to the heart are reduced to an increase of the R, followed by the appearance of preponderance of the left ventricle and by branch block. The *Bacillus botulinus* toxin exerts a damaging action on the sinus node and sino-auricular conduction. The tetanus toxin does not produce distinct changes in the electrocardiogram. Administration of vitamin C has no special influence during the period of poisoning with diphtheria toxin and with *Bacillus botulinus* toxin.

Roentgen Treatment of Malignant Lymphogranulomatosis—Frimann-Dahl says that, while malignant lymphogranulomatosis may be acute, more benign cases also occur with duration of life for years. Cases of actual recovery are doubtful. The average length of life is three years. Roentgen irradiation has a pronounced tendency to prolong life. The shorter the duration of the disease before roentgen treatment is instituted, the longer the life expectancy, the younger the patient and the better his general condition, the more favorable the prognosis probably is. Both local and general roentgen treatment may be effective even when there are large tumor masses. The patient's general condition may be improved and he may be made capable of work for months and years. Recurrences, however, are inevitable, and with every recurrence the treatment becomes less effective. Because of the relatively marked differences in the length of life according to international statistics, the author suggests that perhaps the course of malignant lymphogranulomatosis differs in different countries.

THE DIAGNOSIS AND TREATMENT OF CIRRHOSIS OF THE LIVER IN ITS EARLY STAGES

CLINICAL LECTURE AT ATLANTIC CITY SESSION

THOMAS P. SPRUNT, M.D.
BALTIMORE

The intensive research dealing with the liver during the past two decades has added greatly to our knowledge of the physiology of this important structure. It has emphasized the protean nature of its activities as well as its extraordinary powers of reserve and of regeneration. In certain striking particulars this knowledge has been translated into a great increase in our clinical power, notably in the development of liver extract in the treatment of pernicious anemia. It has taught a great deal about acute diffuse diseases of the liver, and physicians are beginning to acquire more definite knowledge of that important chronic disease cirrhosis, but clinicians as yet have done little to improve their diagnostic acumen regarding the early stages of cirrhosis, in which treatment may be more effective.

In spite of increased knowledge of physiologic chemistry, the most valuable clinical data for the diagnosis of hepatic diseases are still to be obtained by a painstaking clinical history, a careful physical examination and other relatively simple methods of bedside observation. It has been pointed out repeatedly that the most obvious evidences of disease of the liver have to do with the excretion of bile, with its relation to the portal circulation and with its variability in amount. Hence the pathologic factors of jaundice, of portal obstruction and of variations in size, consistency and shape of the liver loom up importantly in bedside examinations and observations.

In many typical cases such methods will suffice, but in other cases the difficulties of differential diagnosis or the wish to make earlier diagnoses has made highly desirable the development of reliable tests of the functional capacity of the liver. Its multiplicity of functions, however, its wide functional interrelationships with other organs and tissues and its great reserve power have handicapped greatly a favorable consummation of this desire. Certainly no single, all-embracing test need be expected. Of the many methods that have been devised to test each of the known functions of the liver, only a few have come into anything like general use, and of these perhaps the more valuable in the diagnosis of cirrhosis of the liver are certain of the excretory tests.

DIAGNOSTIC FACTORS

A brief review of important diagnostic factors may not be amiss.
